Text problem in the book

FOREWORD

The rapid development of the stupendous program of national defense in 1941, plus the mounting needs of the democratic nations at war with the Axis Powers, fostered an unprecedented demand for the mineral raw materials that are indispensable to the successful conduct of modern military operations. As soon as this country entered the worldwide conflict in December, the demand for materials became more acute, and at the same time shipments from foreign sources were seriously curtailed. Under the growing pressure for mineral supplies, especially those in which the resources of the United States are deficient, the Bureau of Mines was called upon to exert its efforts to the utmost in the search for domestic sources of the needed minerals, in developing methods for recovering necessary metals from the low-grade ores available in this country, and in supplying accurate, current, and comprehensive data regarding production, distribution, consumption by uses, and stocks of mineral supplies required for military and civil needs. Moreover, the work of the Bureau on health and safety was stepped up to meet the conditions arising from rapid increase in the productive activities of the mineral industries and the additional hazards resulting therefrom.

The achievements of the mining and metallurgical industries in an attempt to meet the tremendous need for mineral supplies constituted a notable contribution to the remarkable progress of the defense program during 1941 The record of the mineral industries in helping to prepare the country for the eventuality of the war forced upon it on December 7, 1941, is presented and analyzed in the present volume of Minerals Yearbook for the information and guidance of Government, industry, and the general public, both in the present and in future years. Although the bound volume of Minerals Yearbook cannot for the present be released for general distribution because of the confidential material it contains relating to strategic and critical minerals, the several chapters covering the other mineral commodities are printed separately and made available for the use of industry and the general public.

Despite the large increase in the volume of inquiries necessarily imposed by Government upon business in the all-out program of preparation for national defense, the response of the mineral industries and other interests to the fact-finding surveys of the Bureau of Mines has been generous and prompt. It is a pleasure to acknowledge here the cordial assistance of the many individuals and agencies furnishing the data that have enabled the Bureau of Mines to compile this comprehensive record of developments in the mineral industries during the important year of 1941. The limits of space preclude mention of the thousands of contributors to this great fund of factual information, but their assistance has been an indispensable factor of the prepared-

ness program. An especially valuable part of this cooperation is that supplied by State officials who have assisted in collecting mineral statistics within their respective jurisdictions, thus eliminating duplication of effort by State and Federal agencies and promoting more accurate statistics. The State agents cooperating in the 1941 canvass were: Stewart J. Lloyd, acting State geologist, University, Ala.; Herman Gunter, State geologist, Tallahassee, Fla.; Garland Peyton, director, division of mines, mining, and geology, department of natural resources, Atlanta, Ga.; M. M. Leighton, chief, and Walter H. Voskuil, mineral economist, State geological survey division, Urbana, Ill.; A. C. Trowbridge, director, Iowa Geological Survey, Iowa City, Iowa; Raymond C. Moore, State geologist, Lawrence, Kans.; Edward B. Mathews, director, department of geology, mines, and water resources, board of natural resources, Baltimore, Md.; R. A. Smith, State geologist, Lansing, Mich.; H. A. Buehler, State geologist, Rolla, Mo.; Meredith E. Johnson, State geologist, Trenton, N. J.; Jasper L. Stuckey, State geologist, Raleigh, N. C.; Robert H. Dott, director, Oklahoma Geological Survey, Norman, Okla.; E. P. Rothrock, State geologist, Vermillion, S. Dak.; E. H. Sellards, director, bureau of economic geology, Austin, Tex.; Arthur Bevan, State geologist, and Linwood H. Warwick, chief clerk, Virginia Geological Survey, Charlottesville, Va.; Harold E. Culver, supervisor, division of geology, department of conservation and development, Pullman, Wash.; Paul H. Price, State geologist, Morgantown, W. Va.; and E. F. Bean, State geologist, Madison, Wis. In addition, B. D. Stewart, Department of Mines, Juneau, Alaska, and Walter W. Bradley, State mineralogist, San Francisco, Calif., assisted in the compilation of statistics for Alaska and California, respectively.

R. R. SAYERS, *Director*.

CONTENTS

INTRODUCTION

The great increase in the activities of the mineral industries during 1941 in filling the needs of the national defense and lend-lease programs resulted in new annual production peaks for many important minerals. To supply the increasing demands from defense agencies for current information regarding supplies, distribution, uses, and stocks of the needed mineral commodities, the work of the Bureau of Mines was progressively oriented to service in this field. Of the vast amount of new information thus obtained from producers and consumers of mineral products during 1941, much is included in the present Yearbook.

Because of censorship requirements, considerable confusion and delay have been experienced in preparing Minerals Yearbook, 1941. The compilation of Yearbook material has been delayed further by the loss to Federal war agencies of keymen from the commodity divisions of the Economics and Statistics Service. In May the Department of Commerce ceased to publish data covering the export of specific commodities by countries of destination subsequent to March 31. In the latter part of the year it also ruled that all figures of imports and exports later than those covering September should be withheld from publication.

To provide uniform control over the publication and use of Federal statistical information that would give aid and comfort to the enemy, Executive Order 9103 was issued by the President March 18, 1942; it ordered that

> The Director of the Bureau of the Budget shall maintain a continuous surveillance of governmental publication of statistical data and shall determine in any instance whether the publication of statistical data by any Government agency would be in accordance with governmental policy designed to guard against the unauthorized disclosure of vital information as such policy is formulated by appropriate authority.

The Committee on War Information recommended that the Minerals Yearbook be classified by the Bureau of Mines as "confidential," in the military sense of the term, with a limited number of copies distributed for official use only and the remainder of the edition impounded for the duration of the war. However, upon recommendation of the Bureau of Mines, the Bureau of the Budget agreed that only those sections of the Minerals Yearbook dealing with certain mineral commodities designated as strategic or critical by the Army and Navy Munitions Board should be considered confidential. The separate chapters that discuss strategic or critical minerals only are therefore considered confidential, and their distribution is being restricted to a limited list of authorized users in Federal agencies. In those composite chapters of the Yearbook that cover both strategic and critical minerals and others not in such category, discussion of the former is being restricted to material not of a confidential character, and the chapters will be released for general distribution. All other chapters of the Minerals Yearbook will be released for general distribution and will include the customary statistics, with the exception of

data on imports and exports for the last 3 months of the year and those covering exports by countries of destination since March 31.

As Minerals Yearbook, 1941, contains a great deal of information regarding strategic and critical minerals that cannot be released to the public at this time, the volume is issued upon a confidential basis and will be available only to authorized users in Federal agencies having need for the information it contains. The Yearbook will not be available for general distribution until its contents can be made public without disclosing information of significant military value to the enemy.

It will be noted that the continuity of some of the statistical series regularly carried in the Minerals Yearbook has been interrupted necessarily, but temporarily, because of the Government's policy regarding the disclosure of vital information. These interrupted series will be brought up to date in subsequent issues of the Yearbook when the confidential data omitted herein can be released without giving aid and comfort to the enemy.

Acknowledgments.—The collection of economic and statistical data in relation to the bituminous-coal industry was transferred from the Bureau of Mines to the National Bituminous Coal Commission in 1937. Since that transfer, the Yearbook chapters relating to bituminous coal have been kindly contributed by the Commission and its successor, the Bituminous Coal Division, United States Department of the Interior; this cooperation is gratefully acknowledged.

The data on imports and exports in Minerals Yearbook were obtained through the cooperation of the Bureau of Census, United States Department of Commerce.

The Bureau of Mines depends on the good will and voluntary cooperation of those interested in minerals for the data comprised in its statistical program. It is a pleasure to acknowledge the generous support of thousands of individual mine operators, distributors, and consumers, as well as that received from the many public officials and agencies that have returned questionnaires or otherwise supplied information. The Bureau, furthermore, is indebted to a large number of trade associations for liberal contributions of data.

Credit is accorded the many members of the Bureau's staff who assisted in the preparation, editing, and arrangement of the Yearbook material. Especial mention is due the following members of the staff, who have been most active and assiduous in contributing to the preparation of the Yearbook manuscript for publication. Martha B. Clark, besides preparing the statistical summary of mineral production each year, has been largely responsible for the maintenance of continuity of data and uniformity of statistical presentation throughout the Minerals Yearbook volumes. Mabel E. Winslow acted as editorial consultant and was responsible for the editing of the entire manuscript. The Graphic Section of the Bureau, in Pittsburgh, Pa., Louis F. Perry, chief, prepared most of the charts. Max Abel assisted in administrative details of the Yearbook program and had charge of estimates of space requirements for printing. John H. Ady, chief of the Publications Section of the Interior Department and liaison officer between the Department and the Government Printing Office, contributed invaluable counsel in the development and execution of the publishing program.

PART I. GENERAL SUMMARY

REVIEW OF THE MINERAL INDUSTRIES IN 1941

By E. W. Pehrson

SUMMARY OUTLINE

INTRODUCTION

Mineral production in the United States in 1941 responded to the Nation's mobilization for war by exceeding all previous records. The physical volume of production was 7 percent above the previous peak, established in 1940, 17 percent above the predepression peak of 1929, and 49 percent above production levels of the World War of 1917–18. The output was valued at $6,817,300,000, 21 percent above 1940 but 2 percent under the peak value recorded in 1920. Although mineral prices increased moderately in 1941—approximately 9 percent over 1940—the record shows that they were still below the level of prices in general. A heavy demand for minerals persisted throughout the year and in many instances was unsatisfied by available supplies; as a consequence, civilian uses were substantially curtailed to maintain military production schedules. Industry inventories trended downward, and efforts were made to increase production at home and abroad, particularly in Latin America.

The transition from a defense to a war economy in December 1941 had no immediate effect on the domestic mineral industry other than the added impetus for more production prompted by the realization that the Nation was actually at war. The success of Axis aggression and submarine warfare prior to Pearl Harbor had provoked major problems in maintaining supplies of those minerals normally obtained in quantity from the Eastern Hemisphere, so that with the declaration of war plans for meeting this threat were well advanced. The success of the submarine attack on American shipping off the Atlantic coast and in the Caribbean early in 1942 greatly aggravated the situation,

however; in these circumstances it was inevitable that 1942 would bring more rigid Federal controls in the production and distribution of mineral raw materials, as well as greater emphasis on lessening our dependence on distant supplies by development of marginal resources nearer home.

Extension of Axis control of mineral resources.—The success of the Axis conquest, in the light of the relatively small material resources available to it at the beginning of the war, must be acknowledged as an outstanding achievement for the dictator nations and a major setback for the democracies. Not only have these aggressions mitigated to a considerable extent serious deficiencies in minerals for the Axis, but they have also cut off important sources of supply upon which the United Nations have depended for many years. Before their expansion Germany, Japan, and Italy occupied only 3 percent of the land area of the world, comprised only 10 percent of the population, and controlled not more than 5 percent of the mineral wealth. On July 1, 1942, they dominated 13 percent of the land area, 35 percent of the population, and about a third of the mineral resources, and there was no assurance that their aggression would not extend farther before the tide of victory turned. Control of Australia and the isolation of virtually all of Asia and North Africa could not be ruled out as an impossibility at that time.

The direction of Axis expansion has been influenced to a considerable extent by mineral objectives. Hitler's drive to the southeast and Japan's move to the southwest struck at rich and strategic mineral areas that heretofore have contributed much to the industrial strength of the United Nations. The shutting off of supplies of tungsten and antimony from China and of tin, manganese, and chromite, as well as rubber, manila fiber, and other nonmineral commodities from southeastern Asia already constitutes a serious loss, and if the threatened pincer movement on the Indian Ocean isolates the Asiatic Continent the Allies face the loss of more important sources of manganese and chromite, strategic mica, and flake graphite. Russia's military power has been crippled by the loss of the manganese, iron, and coal industries of the Ukraine. At the same time, the most serious deficiency of the Axis—petroleum—has been alleviated in part by Japan's occupation of Malaya and the Netherlands Indies. Germany has obtained valuable raw materials and facilities for manufacturing munitions in Europe and seeks the rich petroleum prizes of the Near East.

The numerical significance of Axis gains in mineral wealth is illustrated by the accompanying table, which shows the percentage of Axis control of world production and capacity in various commodities before expansion began, as of July 1, 1942, based on battle lines on that date, and the possible control that would result from conquest of Australia and isolation of Asia and North Africa by control of the Indian Ocean and the Mediterranean. The figures are based on production in 1940, the latest year for which reliable estimates can be made. They do not reflect the expansion in production that has occurred since 1940 or the effects of "scorched-earth" activities in occupied countries. Consequently the data can be considered only as an approximate indication of relative mineral strength of the antagonists in the present world conflict.

Growth in Axis control of mineral production resulting from conquest, in percent of world total

Mineral	Before expansion	July 1, 1942	Possible[1]	Mineral	Before expansion	July 1, 1942	Possible[1]
Petroleum	1	7	22	Tin	1	72	74
Refinery capacity	5	11	24	Aluminum	33	54	61
Coal	27	53	59	Bauxite	11	49	62
Iron ore	6	46	55	Magnesium	67	68	72
Steel capacity	20	34	44	Manganese ore	2	30	78
Copper	5	10	20	Chromite	3	30	68
Refinery capacity	11	17	21	Tungsten	6	64	67
Lead	7	22	45	Nickel	1	4	12
Zinc	16	27	44	Mercury	52	68	74
Smelter capacity	10	44	51	Antimony	2	32	34

[1] Assuming Australia, Asia, and North Africa come under Axis domination.

As indicated above, the control over mineral resources so far gained by the Axis cannot be considered as an equivalent gain in military power. For example, tungsten and antimony in the interior of China, not yet occupied by Japanese troops, is largely cut off from the United Nations but is only partly available to the Axis. Restoration of production schedules and transportation in newly conquered territory is at best a difficult job, and doubtless many production facilities have been destroyed under the "scorched-earth" programs of the invaded countries. Occasionally refining capacity has been captured, but raw materials to maintain operations are not available. Many of the European oil refineries are reported to be inactive for want of crude petroleum. Despite these difficulties, the improved mineral position of the Axis countries has strengthened their capacity for war and at the same time aggravated the raw-material problems of the United Nations, in consequence prolonging the duration of the conflict.

These losses in mineral supplies, while indeed serious, are by no means decisive. The industrial war power of the United States and its Allies when fully mobilized will outweigh that of the Axis by a considerable margin. Recently the Government advised the Nation that the United Nations war production already has surpassed that of the Axis but that the program must move forward even faster. Potential supplies of all essential minerals are adequate for this purpose. The United States has substantial stocks of many of the strategic minerals, the less essential civilian uses are being curtailed, and production at home and abroad is being stepped up. The immensity and diversity of the mineral wealth of the Western Hemisphere assure ample raw materials for successful prosecution of the war, if new production can be developed in time. Winning the war is thus chiefly a problem of quickly converting potential mineral output into usable material and of speedy organization and efficient use of manpower and plant to employ these mineral materials in effective military effort before the enemy consolidates its holdings and becomes intrenched in impregnable military positions.

PRODUCTION

Value of mineral output.—In 1941, as in 1940, the quantity of minerals produced exceeded all previous records; but the value failed to reach that of the peak year 1920, when prices of minerals, partic-

ularly coal, were abnormally high. The total value of the mineral output of the United States for 1941, approximately $6,817,300,000, was 2 percent below that of 1920 but exceeded all other years. It was 21 percent over 1940. Average prices in 1941 were roughly 9 percent above those in 1940.

Of the total value of mineral production in 1941, fuels contributed $3,628,900,000 (53 percent), metals $2,137,100,000 (31 percent), and nonmetallics other than fuels $1,051,300,000 (16 percent). The value of metal production increased 27 percent, that of fuels 16 percent, and other nonmetallics 28 percent. Figure 1 shows the growth in value of various branches of mineral production from 1880 to 1941. Up to 1908 metals comprised the principal product in most years, but since then fuels have consistently ranked first except for 1915 and 1916. The predominant position of the mineral fuels during the last three decades has been due largely to the phenomenal growth of the petro-

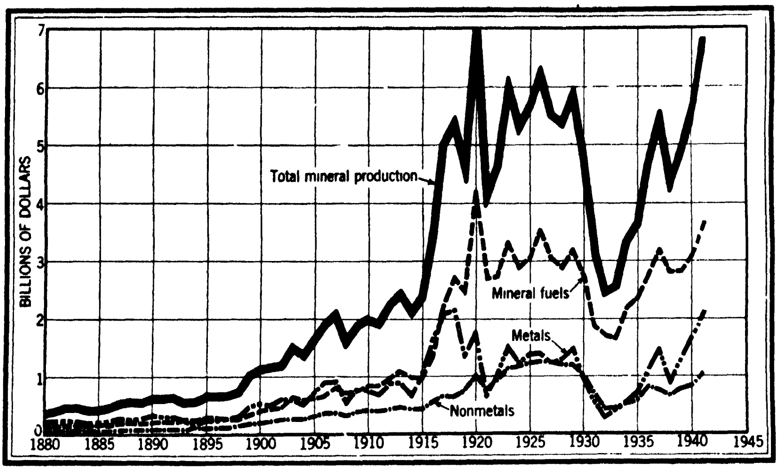

FIGURE 1.—Trends in the value of mineral production in the United States, 1880–1941.

leum and natural-gas industries. In 1941 oil and gas wells contributed products valued at over $2,300,000,000, or 34 percent of the total mineral output.

Trends in physical volume of production.—Figure 2 compares the physical volume of mineral production during the last 42 years with industrial and agricultural production and with population growth, each expressed in terms of an index based on the average for 1935–39.[1] The long-time trend of production during this 42-year period has been steadily upward, although year-to-year and cyclical fluctuations have been prominent. Production of minerals, which furnish tools, fuels, and raw materials for manufacture, has naturally been closely correlated with the trend of industrial production, experiencing the same violent ups and downs, whereas agricultural production has exhibited more moderate fluctuations.

---

[1] The following indexes have been used—volume of farm production, U S. Department of Agriculture; mineral production, 1900–18, from Warren Persons' Forecasting Business Cycles; mineral production of 1919–41 and industrial production, Federal Reserve Board; total population of the United States, Bureau of the Census.

The importance of metals in the manufacture of armament and other defense needs is shown by the sharp up-swing of mineral production between 1914 and 1918 and by the all-time high records established in 1940 and 1941 in both mineral and industrial output. Because production of coal for domestic use and petroleum for automobile fuel, which have a pronounced effect on the trend of mineral output, does not respond proportionately to increases in the rate of manufacturing activity and is more stable, the index of industrial production tends to exceed that of mineral production in periods of prosperity and to fall below during depressions. Thus the sharp

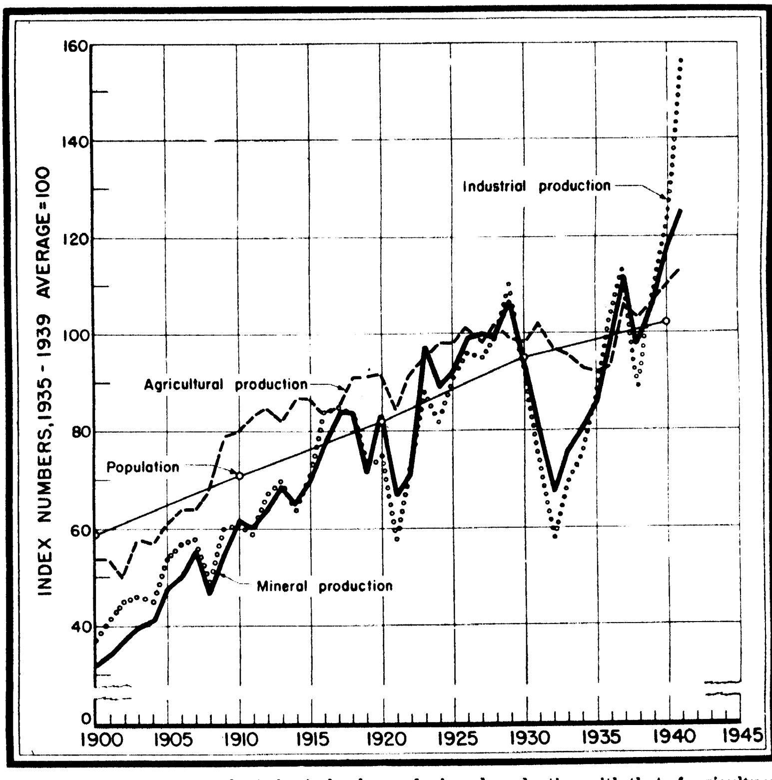

FIGURE 2.—Comparison of growth of physical volume of mineral production with that of agricultural and industrial production and population, 1900–41.

advance of the index of industrial activity over the index of mineral output in 1941 should not be interpreted as a true indication of the lag in mineral output. Such lag as did exist in 1941 was offset in part by larger net imports of mineral raw materials and liquidation of stocks.

STOCKS

Mineral production, particularly of metals, did not pace the rapid increase in manufacture in 1941, and as a consequence inventories trended downward. Industry stocks of copper, lead, and zinc declined during the year, as well as those of manganese, tin, and

mercury. Consumers' stocks of pig iron likewise declined, and the quantity of iron and steel scrap on hand at suppliers' and consumers' plants was considerably lower at the end than at the beginning of 1941. Contrary to the general trend in metal inventories, stocks of tungsten and chromite increased as a result of large importations. Inventories of cement and petroleum decreased somewhat, but those of anthracite and bituminous coal rose appreciably.

Stock-piling activity of the Government was greatly expanded during the year, and the number of commodities being accumulated was increased considerably.

CONSUMPTION

Consumption of minerals exceeded all previous records in 1941, notwithstanding the fact that many less essential civilian uses were curtailed. Despite the frequent cry of shortages, the record shows outstanding increases in consumption to new peaks of virtually all metals and most of the important nonmetallic minerals. Among the metals, iron, copper, lead, zinc, aluminum, magnesium, tin, manganese, chromium, and other alloying elements exceeded former peaks by considerable margins. Domestic demand for petroleum reached a new high at least 55 percent above the 1929 demand. Contrary to the general trend, consumption of anthracite and bituminous coal, though substantially above that in 1940, was still below records set many years ago. The use of cement in 1941 likewise advanced over 1940 but did not equal the predepression high. Other important nonmetallic minerals, however, including raw clay, lime, phosphate rock, salt, sand and gravel, stone, and sulfur, established new peak rates of use in 1941.

The tremendous quantities of minerals consumed in 1941 reflected the rapid rate at which the United States was mobilizing for war. The Federal Reserve Board index of industrial production (1935–39 average=100) again reached a new high by rising from 123 (revised) in 1940 to 156 in 1941. In 1929 the index was 110. Except for a 3-point drop in April, industrial activity continued upward throughout 1941, advancing from 140 (adjusted index) in January 1941 to 168 in December. Aircraft, tanks, ships, guns, and other accouterments of war were substantial contributors to this upward surge; but the abrupt rise in construction, which had lagged behind general industrial activity before 1941, also had an important effect on the demand for minerals. The Federal Reserve Board index of construction contracts awarded (value basis, 1923–25=100) rose from 81 in in 1940 to 122 in 1941—the highest since the peak of 135 established in 1928. However, construction contracts other than residential soared to a peak of 149 compared with 89 in 1940 and 142 in 1929, as a result of the large volume of defense construction inaugurated during the past few years.

PRICES

No precise composite index of average prices of mineral raw materials is available, but a weighted average for 24 major commodities, which comprised approximately 98 percent of the total value of mineral production in 1941, indicates an increase of about 9 percent

in unit sales realizations by producers in 1941 compared with 1940. A somewhat larger rise in fuel and metal prices was offset by only a moderate increase in the unit values of other nonmetallic minerals.

According to the Bureau of Labor Statistics, the wholesale price index (1926=100) of metals and metal products rose from 95.8 in 1940 to 99.4 in 1941. That of nonferrous metals, including some fabricated products, advanced from 81.3 to 84.4. Prices for copper, lead, mercury, tin, and zinc made gains, but that of aluminum dropped again. The index for iron and steel products increased from 95.1 to 96.4; quotations for pig iron and scrap were several points higher, but iron-ore prices again were lower. The fuels were consistent in upward movements. The price index for anthracite rose from 71.7 to 82.7, bituminous coal from 78.9 to 104.3, and petroleum and its products from 50.0 to 57.0. Except for crushed stone, which declined fractionally, building materials (brick and tile, cement, lime, and sand and gravel) recovered somewhat from the lower prices of 1940. Phosphate rock and potash prices likewise rose. The index number of wholesale prices for all commodities increased from 78.6 in 1940 to 87.3 in 1941.

Throughout 1941 mineral prices were under surveillance by the Federal price-control agencies, and much higher prices that would have been justified by supply-demand relationships were avoided, chiefly through voluntary cooperation of the industries. In some instances the Government imposed rigid price ceilings.

Mineral prices in 1941 were still far below previous peaks. The 1941 index for nonferrous metals was 20 percent lower than in 1929 and 42 percent below 1918. The iron and steel index was about 2 percent higher than in 1929 but 34 percent below that in 1918. Prices for petroleum products, although somewhat improved over recent lows, were still 20 percent below 1929 and 58 percent below 1918. The 1941 index for all commodities was 8 percent below 1929 and 34 percent lower than in 1918.

EMPLOYMENT AND SAFETY

Gains in employment noted a year ago for the mineral industries of the United States were continued in 1941; more men were employed at the mines, and more man-hours were worked. Incomplete reports from mines, quarries, mills, smelters, and coke ovens indicate a total of 829,000 men employed, an increase of 27,000 over the number of employees reported for 1940. Even more significant than the increase in number of workers was the increase over 1940 in the number of man-hours worked; the latter amounted to 8 percent and the former to less than 4 percent for all mineral industries combined. Particularly notable were the increases in employment at beehive coke ovens, at mines producing minor but strategic metals such as quicksilver, tungsten, and manganese, and at mines producing such major metals as iron, copper, zinc, and lead. Small gains in man-hours worked were reported for gold lode mines, although gold placer mines reported a decline. Coal mines—both bituminous and Pennsylvania anthracite—also reported more man-hours of work; but these gains, although larger in actual number of man-hours because employment in coal mining is the largest among the various mineral industries, were

proportionately smaller than those at some classes of mines engaged in the production of metallic ores.

Fewer deaths were caused by accidents in the mineral industries of the United States in 1941, but this gratifying decline was offset by an increase in the number of nonfatal injuries. The chief reason for the decline in fatalities was the reduction in deaths from major disasters in coal mines—disasters in which five or more lives are lost. Whereas six major disasters causing 276 deaths in all occurred in 1940, reports for 1941 showed eight disasters with 73 deaths resulting therefrom. This improvement in the major-disaster situation caused the over-all death toll of the mineral industries to drop from 1,716 in 1940 to an estimated 1,620 in 1941. All of the major disasters in 1941 occurred in bituminous-coal mines; none has occurred in a Pennsylvania anthracite mine since June 2, 1938.

The combined fatality rate for all mineral industries in 1941 was 1.16 per million man-hours worked, which compared favorably with a rate of 1.33 for 1940. The corresponding rate for nonfatal injuries was 65.11, as against 64.08 for the previous year. This rise in accident frequency probably resulted from the intense pressure on the mineral industries for production in 1941, which necessitated the employment of inexperienced help at many mines.

Nearly all branches of the mineral industries—such as coal mines, copper mines, iron mines, and limestone quarries—had higher accident-frequency rates in 1941 than in 1940. However, lower and therefore more favorable rates were reported at lead-zinc mines in the Mississippi Valley States, slate quarries, and ore-dressing plants.

On May 7, 1941, Congress enacted a coal-mine inspection law, which, among other things, required the Bureau of Mines to obtain additional information concerning accidents in coal mines. Expanded surveys began April 1, 1942. It is expected that the accident facts now being reported will, under a continuing analysis, prove helpful in achieving the main objectives of the law—namely, the prevention of accidents and the lowering of accident costs that have heretofore been associated with the production of coal in the United States.

Accidents to workers engaged in the production of petroleum—a mineral vital to mechanized warfare—have never been reported systematically. A survey of accident frequency during the calendar year 1941 was begun by the Bureau of Mines in the spring of 1942. Early reports indicate that accidents during 1941 occurred at a rate of 20.21 for each million man-hours of work performed at the producing properties.

NATIONAL DEFENSE ACTIVITY

The progress of World War II, culminating in the declaration by the United States of war against the Axis Powers in December 1941, promoted rapid expansion of the Government's organization for industrial mobilization. A brief summary of activities pertaining to the mineral industry, which appeared in this chapter of Minerals Yearbook—Review of 1940, is carried forward in the following digest of subsequent developments up to about August 1, 1942.

At the beginning of 1941 administration of the mineral aspects of the Government defense program was lodged in a variety of temporary agencies, including the Office for Emergency Management, Office of

Production Management, Advisory Commission to the Council of National Defense, Administrator for Export Control, Office for Coordination of Commercial and Cultural Relations between the American Republics, National Defense Research Committee, Metals Reserve Co., and Defense Plant Corporation. Besides these, the permanent Government agencies had greatly expanded their activity in the mineral field.

The temporary agencies were reorganized during the year to meet changing conditions, and several new ones were created. By the end of 1941 all original functions of the Advisory Commission to the Council of National Defense had been transferred to other agencies, so that the Commission became virtually nonexistent. The Office of the Administrator for Export Control was transferred to a new Economic Defense Board on September 15, 1941, which agency became the Board of Economic Warfare on December 17, 1941. The Office for Coordination of Commercial and Cultural Relations Between the American Republics, formerly part of the National Defense Council, was transferred on July 30, 1941, to the Office for Emergency Management under the title of Office of the Coordinator of Inter-American Affairs. The National Defense Research Committee, created by the Council of National Defense in June 1940, was transferred on June 28, 1941, to the newly organized Office of Scientific Research and Development under the Office for Emergency Management. Another new agency created during 1941 was the Office of Price Administration and Civilian Supply, which on April 11. 1941, absorbed the Price and Consumer Divisions of the National Defense Advisory Commission but on August 28, 1941, was succeeded by the Office of Price Administration, under the Office for Emergency Management; at this time the civilian supply functions were transferred to the Office of Production Management. The Office of Petroleum Coordinator for National Defense (later War) was established on May 28, 1941, with the Secretary of the Interior designated as Coordinator. On November 5, 1941, the Secretary of the Interior also was requested to serve as Coordinator of Solid Fuels. Other agencies created in 1941 with functions more indirectly related to the mineral industries included the National Defense Mediation Board, which was succeeded on December 17, 1941, by the National War Labor Board; Office of Lend-Lease Administration; Supply, Priorities, and Allocations Board; Office of Defense Transportation; Office of Censorship; and others of minor significance to the mineral industries.

Some of the afore-mentioned agencies were created after the declaration of war on December 8, 1941. On January 16, 1942, the War Production Board replaced the Office of Production Management, and the Supply, Priorities, and Allocations Board, which had been set up as a superagency, with Donald M. Nelson as Chief, to determine policy for and coordination of the various activities relating to supply of materials and commodities and their allocation to defense and civilian uses. A War Manpower Commission was established on April 18, 1942, with Paul V. McNutt as Chairman, to formulate plans and programs and establish basic national policies to assure the most effective mobilization and maximum utilization of the Nation's manpower in the prosecution of the war. The labor supply and training functions of the Labor Division of the War Production Board were

transferred to the new agency, as well as related activities of other Government agencies operating in the employment field.

Office for Emergency Management.—This is essentially an administrative agency of the Executive Office designed to maintain liaison between the President and the national war agencies. During 1941 most of the temporary defense and war bureaus were coordinated through the Office for Emergency Management, and by the end of the year all the functions of the Advisory Commission to the Council of National Defense had been transferred to agencies under its jurisdiction.

War Production Board.—At the close of 1941 the Office of Production Management, predecessor of the War Production Board, was operating under the supervision of William S. Knudsen, Director General, and Sidney Hillman, Associate Director General. The organization had been expanded from its original four divisions—Production, Priorities, Purchases, and Labor—to include the following bureaus and divisions:

Bureau of Clearance of Defense Industry Advisory Committees—Sidney J. Weinberg, Chief.
Bureau of Industrial Conservation—Lessing J. Rosenwald, Chief.
Bureau of Research and Statistics—Stacy May, Chief.
Production Division—W. H. Harrison, Chief.
Purchases Division—Douglas MacKeachie, Chief.
Priorities Division—Donald M. Nelson, Chief.
Labor Division—Sidney Hillman, Chief.
Division of Contract Distribution—Floyd B. Odlum, Chief.
Division of Civilian Supply—Leon Henderson, Chief.
Materials Division—W. L. Batt, Chief.

Coincident with the creation of the War Production Board in January 1942, William S. Knudsen was appointed Director of Production for the War Department, with the rank of Lieutenant General. Donald M. Nelson was designated as Chairman of the War Production Board. Other members of the Board as of June 1942 were:

Secretary of War.
Secretary of the Navy.
Federal Loan Administrator.
Lieutenant General in charge of War Department production.
Administrator, Office of Price Administration.
Chairman, Board of Economic Warfare.
Director, Labor Division, War Production Board.
Special Assistant to the President.

A few changes were made in the general organization of the Board. As of June 1942 a Requirements Committee (W. L. Batt, Chairman) and a Planning Committee (Robert R. Nathan, Chairman) had been established in the office of the Board Chairman. The Bureau of Clearance of Defense Industry Advisory Committees, the Priorities Division, and the Division of Contract Distribution were consolidated in a Division of Industry Operations with J. S. Knowlson as Director. The other divisions and bureaus of the original Office of Production Management were continued with relatively minor internal adjustments. A. I. Henderson succeeded W. L. Batt as Chief of the Materials Division, and Wendell Lund replaced Sidney Hillman as Chief of the Labor Division.

Most of the activity of the War Production Board concerned with production and distribution of mineral raw materials was centered in

the Materials Division, in which Dr. C. K. Leith served as technical consultant. As of May 1942, the various branches dealing with minerals and their respective chiefs were as follows:

Mining—Dr. Wilbur Nelson.
Stock Pile and Shipping—Dr. William Y. Elliott.
Aluminum and Magnesium—A. H. Bunker.
Chemicals—Dr. Ernest W. Reid.
Iron and Steel—C. E. Adams.
Power—J. A. Krug.
Cork and Asbestos—Fred W. Gardner.
Nickel—H. A. Rapelye.
Tungsten and Molybdenum—M. K. Smith.
Copper—H. O. King.
Zinc—David A. Uebelacker.
Manganese and Chromite—Andrew Leith.
Tin and Lead—Erwin Vogelsang.
Mica and Graphite—Raymond B. Ladoo.
Miscellaneous Minerals—Richard J. Lund.

Office of Price Administration.—Surveillance and control of mineral and scrap metal prices were greatly increased during 1941 as the gaps between supply and demand widened and pressure on prices mounted. Several warnings were issued during the year to discourage upward trends in prices, and several ceilings were imposed. Before passage of the Emergency Price Control Act of 1942, approved January 30, 1942, the agency functioned only under general executive orders, but passage of the act established definite statutory authority for enforcement of price-stabilization measures. The general policy of the Office of Price Administration has been to pay a premium over fixed ceiling prices for submarginal production rather than to stimulate output by a general advance in price levels. Details on the various actions taken during the year are given in the commodity chapters of this volume.

Control of mineral prices is administered through the Industrial Materials Price Division (Clair Wilcox, Director), the Fuels Price Division (George W. Stocking, Chief), and the Industrial Manufacturing Price Division (Donald Wallace, Director). Donald D. Kennedy heads the Iron and Steel Branch of the Industrial Materials Price Division, John Sumner the Zinc, Lead, and Tin Branch, and Carl Holmquist the Copper, Aluminum, and Ferro-alloys Branch; Jesse L. Maury is Chief Premium Price Analyst for copper, lead, and zinc. R. G. Phelps is Chief of the Chemicals Branch of the Industrial Manufacturing Price Division.

Board of Economic Warfare.—Besides exercising control of all foreign trade in minerals, the Board of Economic Warfare plans Government activities in the procurement, development, and production of minerals required from foreign countries for war purposes. The last function is administered through a Metals and Minerals Division, of which Alan M. Bateman is Chief. The Division is composed of the following sections:

Major Ferro-alloys Section—Robert H. Ridgway, Chief.
Minor Ferro-alloys Section—Hugh E. McKinstry, Chief.
Major Base Metals Section—Herman L. Dauth, Chief.
Minor Base Metals Section—William Warfield, Chief.
Minor and Rare Metals Section—James S. Baker, Chief.
Nonmetallic Mineral Section—Paul M. Tyler, Chief.

As of August 1, 1942, the Board of Economic Warfare had mineral missions in Africa, Argentina, Brazil, Central America, Colombia, Cuba, Guatemala, Mexico, and Peru.

Office of Petroleum Coordinator for War.—This office was authorized by the President to coordinate all Federal activities concerned with the production, refining, transportation, and marketing of petroleum, particularly where these functions pertain to war. It functions as a clearing house for the Federal Government on petroleum matters and operates closely with an Industry War Council, of which W. R. Boyd, Jr., President of the American Petroleum Institute, is Chairman. The organization and major officials of the Office of Petroleum Coordinator for War, as of August 1, 1942, were:

Coordinator—Harold L. Ickes.
Deputy Coordinator—Ralph K. Davies.
Production Division—Don R. Knowlton, Director.
Refining Division—Wright W. Gary, Director.
Transportation Division—J. R. Parten, Director.
Marketing Division—Robert T. Collier, Director.
Natural Gas and Natural Gasoline Division—E. Holley Poe, Director.
Foreign Division—James Terry Duce, Director.
Petroleum Reserves Division—W. B. Heroy, Director.
Petroleum Supply Division—Robert L. Minckler, Director.
Materials Division—Greer W. Orton, Director.
Facility Security Division—W. D. Mason, Director.
Research Division—Edward B. Swanson, Director.
Public Relations Division—Gordon M. Sessions, Director.

Field representation for the Petroleum Coordinator's Office is provided through five district offices and district industry committees with headquarters at New York, N. Y.; Chicago, Ill.; Houston, Tex.; Denver, Colo.; and Los Angeles, Calif.

Office of Solid Fuels Coordinator for War.—This office serves as the agency for the coordination of information and the making of recommendations concerning measures relating to the production, storage, pooling, transportation, distribution, marketing, and consumption of solid fuels for the purpose of assuring adequate supplies at reasonable prices for military, industrial, and civilian needs. As of August 1, 1942, the office was operating under the following administrators:

Coordinator—Harold L. Ickes.
Deputy Coordinator—Howard A. Gray.
Associate Director for Bituminous Coal—Thomas J. Thomas.
Associate Director for Transportation—Ralph P. Russell.
Assistant Director for Anthracite—Brice P. Disque.
Assistant Director for Coke—Harlen M. Chapman.

Bureau of Mines.—Through its field investigations, technical research, health and safety, and economics and statistics services, the Bureau has made valuable contributions to the war program too numerous to mention in detail in this summary. Considerable information on the Bureau's war activity as regards individual commodities is given in the various chapters of this volume. Perhaps the most significant accomplishments are those resulting from the investigation of domestic resources of strategic minerals initiated in 1939 under Public Law 117, 76th Congress, and subsequently extended to other critical minerals. Under this program approximately 1,600 deposits had been investigated up to June 30, 1942. Exploration projects were undertaken on 96 of the most promising, and of these, 56 have proved successful to the extent that tonnages of ore have been developed that are already being brought into production or can be if needed for emergency purposes. The Bureau engineers estimate that the program has indicated 56,000,000 tons of ore of commercial or near-commercial grade in the following categories:

Type of ore	Indicated ore reserves	Approximate grade
	Short tons	
Antimony	2, 241, 600	2 percent antimony.
Chromite	4, 104, 500	20 percent Cr_2O_3
Manganese	10, 239, 900	20 percent manganese
Mercury	1, 053, 100	2 pounds of mercury per ton.
Nickel	8, 406, 700	0 35 percent nickel
Tin	68, 000	6.33 pounds of tin per ton.
Tungsten	1, 094, 200	0 8 percent tungsten
	Long tons	
Iron (Western States)	28, 090, 300	50 percent iron.
	Short tons	
Bauxite	1, 165, 000	40 percent plus Al_2O_3

Geological Survey.—The activities of the Geological Survey have been largely oriented to war work. Its geologic staff is playing an important part in the exploration for war minerals, and its Conservation Branch is aiding in increasing mineral production from public lands. The Survey's map-making and topographic-mapping facilities are working in close cooperation with the military establishments, and its ground-water experts are assisting in solving problems of water supply for military cantonments and munitions plants.

The Survey conducts three types of geological investigations. Regional or district studies of promising areas are made with a view to recommending deposits worthy of further exploration and development by the Bureau of Mines. A second type is carried on by the geologists assigned to Bureau of Mines projects, who assist in planning explorations and interpreting the results. A third type consists of brief examinations of districts or individual deposits for a specific purpose; these usually are requested by some other war agency. The results of this work are published in a series of Strategic Mineral Investigations, of which about 50 had been printed up to June 30, 1942.

Metals Reserve Co.—The Metals Reserve Co., which was transferred from the Federal Loan Agency to the Department of Commerce on February 24, 1942, is the agency through which the Government finances the procurement of mineral supplies and the payment of premium prices. The company is acquiring reserve stocks of various minerals as available supplies permit. In the acquisition and distribution of these materials to industry, the company works in cooperation with the War Production Board, the Office of Price Administration, and the Board of Economic Warfare. Chief administrative officials and mineral advisers include:

Chairman of the Board—Jesse H. Jones.
President—Charles B. Henderson.
Executive vice president—G. Temple Bridgman.
Assistant vice president—Simon D. Strauss.
Technical advisers—H. DeWitt Smith and D. D. Irwin.
Consulting engineer—John E. Norton.
Special adviser—Howland Bancroft.

Defense Plant Corporation.—This agency also was transferred from the Federal Loan Agency to the Department of Commerce on February 24, 1942. The Corporation has very broad authorization, but is chiefly concerned with Government financing of new productive capacity required for war purposes. It operates under directives from the War Production Board, War and Navy Departments. Mineral projects financed by the Corporation include construction

of plants for the production and processing of ores of aluminum, magnesium, chromium, manganese, tungsten, vanadium, and other minerals, as well as steel and pig iron plants. Jesse H. Jones is Chairman of the Board, and Sam H. Husbands is President.

GOVERNMENT STOCK PILES

Government purchasing of minerals for stock piling and for the purposes of price control and stimulation of production has been greatly expanded since January 1, 1941. At that time the Navy Department had completed its small mineral stock-piling program, which included purchases of chromium ore, manganese ore, tin, and tungsten ore. The Procurement Division of the Treasury Department, operating under Public, No. 117, 76th Congress, was actively engaged in acquiring stocks of chromium ore, manganese ore, mercury, mica, quartz crystals, tin, and tungsten ore. Its tin program was completed and purchase of industrial diamonds was inaugurated during the first half of 1941. As stated in Minerals Yearbook, Review of 1940, the need for acceleration and expansion of stock-piling activity became apparent as the war in Europe took a serious turn with the fall of France in May 1940, and this need was met by establishing subsidiary buying organizations in the Reconstruction Finance Corporation of the Federal Loan Agency. With the exception of nitrate of soda, which was acquired by Defense Supplies Corporation, all Reconstruction Finance Corporation metal and mineral purchases have been made through the Metals Reserve Co. As of the close of business September 13, 1941, the Metals Reserve Co. announced it had made commitments to acquire minerals and metals at a cost estimated at $969,544,000.

The extent to which Government purchases have expanded is indicated by the following lists, which show the commodities being acquired at various times:

As of the end of 1940	*Added in 1941*	*Added in January–July 1942*
Antimony	Aluminum (refined)	Alumina
Chromium ore	Asbestos	Alumina hydrate
Graphite	Bauxite	Aluminum (reclaimed)
Manganese ore	Beryllium ore	Antimony ore
Mercury	Cadmium	Arsenic
Mica	Cobalt	Bismuth
Quartz crystals	Copper (refined)	Columbite
Tin	Corundum ore	Copper matte
Tungsten ore	Diamonds, industrial	Copper ore
	Iridium	Cryolite ore
	Iron ore	Fluorspar
	Kyanite	Lead (bullion)
	Lead (refined)	Molybdenite
	Lead ore	Nickel (matte)
	Lead vanadate concentrates	Sapphire (natural Montana)
	Nickel (refined)	Silver (foreign)
	Nitrate of soda	Tantalite
	Platinum	Vanadium ores
	Rutile	Zinc (refined)
	Scrap iron	
	Tin ore	
	Zinc concentrates	
	Zirconium ores	

Details of Government purchases during 1941, insofar as they can be revealed in this volume, are shown in the various commodity chapters.

STIMULATION OF DOMESTIC PRODUCTION

The policy of increasing production of minerals through direct Government contract or subsidy rather than by broadcasting general appeals to the public, as was done during World War I, was continued in 1941. The Government program is carried out chiefly through the Metals Reserve Co. and the Defense Plant Corporation, both subsidiaries of the Reconstruction Finance Corporation. Throughout the year prospective producers or producers desiring to increase their capacity received Government help either through loans or advance contracts guaranteeing a market for fixed tonnages at fixed prices. As an added incentive to stimulate copper, lead, and zinc production and as a means of offsetting rising costs that threatened many producers, a premium-price quota plan for these metals was announced jointly by the Office of Price Administration and the Office of Production Management in January 1942. The plan provided for payment of substantial premiums over established ceiling prices for production in excess of quotas which were determined for each producer according to circumstances surrounding his individual operation. The Metals Reserve Co. participated in the administration of the program.

Early in 1942 it became evident that direct methods of assisting small-scale producers were required, and on March 5, 1942, the Metals Reserve Co. announced a program for buying truckload lots of chromium ore at local buying stations established in Oregon and northern California. Specifications were modified to permit purchase of lower-grade ores, and a fixed schedule of buying prices at purchase depots was published. Subsequently, similar depots were set up in Arizona, Arkansas, Colorado, Montana, Nevada, New Mexico, New York, and Tennessee, and small-lot buying was extended to manganese ore and mercury.

Regulations governing Federal loans to mining also were modified in an endeavor to stimulate domestic production. On March 27, 1942, the Reconstruction Finance Corporation announced that owners or lessees of mining property that gives reasonable promise of success could thereafter obtain development loans repayable out of proceeds from production, rather than secured by mortgage on the property. These loans would be made initially in amounts not exceeding $20,000, but if the results of such development were favorable, additional loans up to $20,000 might be made for further development. Public Law 603, approved June 11, 1942, authorized the Reconstruction Finance Corporation to make loans not to exceed $5,000 to any one borrower for the purpose of financing the unwatering, retimbering, making accessible, or other preliminary development of mine workings, when such loans are deemed by the Reconstruction Finance Corporation to be advantageous to the national defense.

PROCUREMENT OF MINERALS FROM LATIN AMERICA [1]

The impact of war between the United States and the Axis Powers has emphasized the seriousness of the economic problems involved in the necessary shift from our peacetime efforts to sell our products in foreign markets to the wartime necessity of purchasing essential

[1] Contributed by J. S. McGrath.

strategic materials. During 1941 the United States Government and private industry literally combed Latin America to locate additional sources of strategic minerals. Intensive efforts were also made throughout the year by the Governments of most Latin American countries to stimulate production of strategic and critical minerals essential to our war effort in areas already under development. Latin America has been a traditional source of many mineral raw materials, which the United States has in inadequate amounts and consequently has been obliged to import. During the present emergency the United States will depend for a large percentage of its total imports of certain minerals on the other American republics.

In the initial stages of the defense program efforts were made by the Government to purchase essential raw materials from the other American republics. However, the high standards of specifications established by the Army and Navy Munitions Board for stock-pile purchases, the narrow list of commodities listed by the Board, and the comparatively small amount of money originally available for such purposes prevented procurement on a large scale. The buying program, later initiated by the Federal Loan Agency, overcame most of the restrictive features of the original purchasing program, and agreements then entered into between the Government of the United States and several Governments of Latin America during 1941 resulted in a substantial increase in the purchases of several urgently needed raw materials. As requirements for such materials soared, plans were developed for buying all strategic minerals available for export in the several countries of Latin America. During most of 1941 the agreements negotiated had an obvious preclusive element in the sense that such over-all agreements to purchase the entire output of a given country would naturally reduce the amount available to other countries. However, in the negotiations for the purchase of strategic materials, emphasis was placed on the definite requirements of the United States rather than on an effort to obstruct purchases by other countries.

The first over-all agreement to purchase all available minerals was negotiated with Brazil in May 1941. The Federal Loan Agency, through the Metals Reserve Co., agreed to purchase the entire exportable surplus of various Brazilian products for 2 years from the date of the agreement. The mineral products involved included bauxite, beryl ore, chromite, ferronickel, industrial diamonds, manganese, mica, quartz crystals, rutile, and zircon. The list was not rigid, and it was anticipated that other commodities would be added as occasion arose. The agreement embodies a prohibition against the export of the commodities specified except to the United States or to other American republics having parallel systems of export control. However, the Metals Reserve Co. was obligated to buy all the enumerated minerals not purchased by private industry in the United States or by other American republics. The mutual benefits to Brazilian producers and industrial consumers of the United States cannot be fully evaluated at this time, but it is expected that the more stable market assured Brazilian producers for 2 years at relatively high prices will have the effect of increasing output.

An over-all agreement with Mexico became effective on July 15, 1941. The arrangement with Mexico followed the same general pat-

tern as in the case of Brazil. The agreement with Mexico consists of two parts. The Mexican Government established an export embargo to all countries outside the Americas and to countries that have not established export controls similar to Mexico. Among the commodities affected are the following minerals: Antimony, arsenic, bismuth, cadmium, zinc, cobalt, copper, fluorspar, tin, graphite, manganese, mercury, mica, molybdenum, lead, tungsten, and vanadium. The Metals Reserve Co. agreed, during a period of 18 months from the date the joint agreement became effective, to purchase the exportable surplus of the commodities specified, provided the sellers were unable to dispose of their products through regular commercial channels after due effort. There are two notable differences between the Mexican and Brazilian agreements. The Mexican agreement is effective for 18 months while the Brazilian agreement is for 2 years; in the Brazilian agreement purchases will be made at fixed minimum prices, while the Metals Reserve Co. agreed in effect to pay current market prices for such materials as it may buy from Mexico.

In October 1941 arrangements were concluded involving an over-all agreement with the Peruvian Government whereby certain strategic and critical materials were made available exclusively to the countries of the Western Hemisphere, with emphasis on the requirements of the United States. This agreement covers antimony, copper, lead, tungsten, vanadium, and zinc; the Metals Reserve Co. will purchase the entire output of these for the Government stock pile, and it is understood that such purchases will be the surplus over and above purchases made by private industry in the United States.

In May 1941 the Metals Reserve Co. entered into a contract with Bolivian producers guaranteed by the Bolivian Government to purchase the entire production of Bolivian tungsten for the next 3 years at $21 per short-ton unit. Late in 1940 the Metals Reserve Co. contracted with tin-ore producers of Bolivia for annual delivery to the United States during the following 5 years of tin concentrates equivalent to 18,000 tons of refined tin a year; the Bolivian Government guaranteed the performance of this contract.

Other contracts negotiated with Bolivian producers by the Metals Reserve Co provide for the procurement of the entire exportable surpluses of Bolivian antimony, lead, and zinc.

At the close of 1941 negotiations were under way leading toward over-all purchasing agreements involving the mineral output of Argentina and Chile.

When negotiations with other American republics, now under way, have been completed and those already concluded have the anticipated effect, it is apparent that the United States will have virtually the entire exportable surplus of strategic minerals produced throughout Latin America.

STATISTICAL SUMMARY OF MINERAL PRODUCTION

(GENERAL UNITED STATES SUMMARY AND DETAILED PRODUCTION BY STATES)

By MARTHA B. CLARK

SUMMARY OUTLINE

INTRODUCTION

This report continues the series of annual statistical summaries published in previous years as chapters of Mineral Resources and Minerals Yearbook.

UNIT OF MEASUREMENT

The unit of measurement used by the Bureau of Mines for each mineral product in reports on the mineral resources is that common to the industry concerned, and the variation in these units makes it impracticable, if not impossible, directly to combine and compare the different minerals except as to value. Although most of the products are measured by weight, some are measured by volume and some by number of "pieces," etc.; for some no total quantity figures are available.

ELIMINATION OF DUPLICATION

In the totals for the United States, shown in the following "general" tables, duplication has been eliminated wherever practicable, and in the State totals given in the State tables virtually all duplication has been eliminated. For instance, in both general and State tables the output of coke is shown but its value is not included in the totals, as the value of the coal used in its manufacture enters into the value of the coal production which is included in the totals. For asphalt, both native and oil are shown in the general tables, but the value of the oil asphalt is excluded from the totals as it duplicates that of the petroleum from which it is manufactured. For the clay industries, no figures have been available for total clay produced. For years before 1936, the total value of clay products is included in both general and State totals as representing the first marketable form of the greater part of the clay produced; the quantity and value of the clay mined and sold in the raw state by miners to users of clay are shown separately also, but the value is not included in the totals as it is duplicated largely in that for clay products. For years beginning with 1936, as the Bureau of Mines believes that a closer approach to

the value of domestic clay in its first marketable form results from the inclusion of the value of clay sold by producers and of clay products other than pottery and refractories, the United States and State totals include such values for the clay industries. This change in practice should be borne in mind when comparing the values beginning 1936 with those for earlier years.

United States totals.—In the general tables both iron ore and pig iron are shown, but the value of the pig iron rather than the iron ore is included in the United States totals, as that is considered the better means of presenting the statistics for iron in its first marketable form. For gold, silver, copper, lead, and zinc the value of "smelter output" is included in the general totals, and to account more fully for the value of the ores treated these smelter figures are supplemented by the value of the byproduct sulfuric acid. The value of pigments (white lead, red lead, lithopone, litharge, and orange mineral) manufactured from metals is not included in the general tables, as the base from which they are made is included in the output of lead or zinc, whereas the value of sublimed blue lead, sublimed white lead, leaded zinc oxide, and zinc oxide is included, as these are made in large part direct from the ores and do not enter into the lead or zinc totals, which represent smelter output.

State totals.—In the State tables also iron ore and pig iron are both shown. As blast-furnace products cannot be traced to the States in which the ore is mined, the value of the ore is used in the State totals. For ores of gold, silver, copper, lead, and zinc no values are shown, and in fact none are recorded; instead, for each of these metals the recoverable content of the ores is used as the basis of valuation. The value of the zinc and lead pigments is not included in the State total, as the recoverable zinc and lead content of the ores from which the products were made is included under zinc or lead. The value of the sulfuric acid produced as a byproduct of copper and zinc smelting and zinc roasting is not included in the State total, as tracing this product back to the State producing the ore has not been possible.

GENERAL TABLES

Mineral products of the United States, 1939–41 [1]

Product	1939 Quantity	1939 Value	1940 Quantity	1940 Value	1941 Quantity	1941 Value
METALLIC						
Aluminum ... pounds	327,090,000	$64,600,000	412,560,000	$75,292,000	(2 3)	(2 3)
Antimonial lead ... short tons (2,000 pounds)	[4] 21,995	(4)	[4] 29,762	(4)	[4] 40,237	(4)
Antimony:						
Metal ... do	(5)	(5)	(5)	(5)	(2 3)	(2 3)
Ore and concentrates ... do	3,174	37,200	1,124	72,900	(2 3)	(2 3)
Bauxite ... long tons (2,240 pounds)	375,301	2,166,236	434,988	2,578,968	(2 3)	(2 3)
Beryllium ore (beryl) ... short tons	95	2,720	121	3,721	158	$7,300
Cadmium:						
Metal ... pounds	5,190,273	2,776,224	6,467,260	4,527,082	7,044,417	5,498,404
In compounds ... do	401,200	212,636	205,900	144,130	265,700	207,246
Chromite ... long tons	3,614	46,892	2,662	28,784	(2 3)	(2 3)
Copper,[6] sales value ... pounds	1,425,349,488	148,236,000	1,818,167,516	205,453,000	1,932,144,953	227,993,000
Ferro-alloys ... short tons	942,101	76,156,588	1,292,660	128,127,810	(2 3)	(2 3)
Gold [7] ... troy ounces	5,611,171	196,391,000	6,003,105	210,108,700	5,976,419	209,174,600
Iron:						
Ore [8] ... long tons	54,827,100	158,537,696	75,198,084	[8] 189,086,799	93,053,994	[8] 249,705,903
Pig ... short tons	35,942,463	626,824,690	46,958,929	840,442,032	55,223,641	1,111,811,316
Lead (refined),[6] sales value ... do	420,967	39,571,000	433,065	43,307,000	470,517	53,639,000
Magnesium (new ingot) ... pounds	10,650,121	(9)	12,823,633	[10] 3,462,380	(2 3)	(2 3)
Manganese ore (35 percent or more Mn) ... long tons	29,307	794,746	40,123	1,169,024	(2 3)	(2 3)
Manganiferous ore (5 to 35 percent Mn) ... do	709,247	2,148,321	1,136,547	3,348,042	(2 3)	(2 3)
Mercury:						
Metal ... flasks (76 pounds net)	18,633	1,936,714	37,777	6,681,618	(2 3)	(2 3)
Ore ... short tons	(11)	(12)	(11)	(12)	(11)	(12)
Molybdenum ... pounds	32,415,000	22,157,000	25,329,000	17,189,000	(2 3)	(2 3)
Nickel ... short tons	394	(9)	554	(9)	(2 3)	(2 3)
Ores (crude), old tailings, etc.:						
Copper ... do	55,221,000	(12)	69,278,000	(12)	78,453,000	(12)
Dry and siliceous (gold and silver) ... do	19,467,000	(12)	18,700,000	(12)	17,639,000	(12)
Lead ... do	5,387,000	(12)	6,144,000	(12)	6,151,000	(12)
Lead-copper ... do	8,000	(12)	10,000	(12)	6,000	(12)
Zinc ... do	7,576,000	(12)	9,521,000	(12)	10,492,000	(12)
Zinc-copper ... do	67,000	(12)	79,000	(12)	81,000	(12)
Zinc-lead ... do	11,518,000	(12)	12,866,000	(12)	16,211,000	(12)
Zinc-lead-copper ... do	12,000	(12)	4,000	(12)	1,000	(12)
Platinum metals (refined) (value at New York City) ... troy ounces	41,441	1,566,000	47,339	1,986,000	(2 3)	(2 3)
Selenium ... pounds	345,726	(9)	368,709	(9)	681,650	(9)

See footnotes at end of table.

Mineral products of the United States, 1939–41—Continued

Product	1939 Quantity	1939 Value	1940 Quantity	1940 Value	1941 Quantity	1941 Value
METALLIC—continued						
Silver [13] ... troy ounces	65, 119, 513	$44, 202, 279	69, 585, 734	$49, 483, 189	72, 336, 029	$51, 438, 954
Tantalum ore ... pounds	340	200			250	280
Tellurium ... do	63, 431	([9])	88, 996	([9])	239, 983	([9])
Tin (metallic equivalent) ... short tons	38	38, 400	55	54, 900	([2, 3])	([2, 3])
Titanium ore:						
Ilmenite ... do	([9])	([9])	([9])	([9])	([9])	([9])
Rutile ... do	([9])	([9])	([9])	([9])	([9])	([9])
Tungsten ore (60-percent concentrates) ... do	4, 287	4, 402, 182	5, 319	6, 576, 318	([2, 3])	([2, 3])
Uranium and vanadium ores ... do	279, 354	1, 053, 660	96, 345	1, 018, 600	([2, 3])	([2, 3])
Zinc,[8] sales value ... do	491, 058	51, 070, 000	589, 988	74, 338, 000	652, 599	97, 890, 000
Other metallic [14]		1, 110, 817		1, 162, 558		1, 727, 828
Total value of metallic products (approximate)		1, 291, 700, 000		1, 679, 500, 000		2, 137, 100, 000
NONMETALLIC						
Arsenious oxide ... short tons	22, 439	495, 500	23, 339	561, 300	34, 784	1, 119, 320
Asbestos ... do	15, 459	512, 788	20, 060	674, 508	([2, 15])	([2, 15])
Asphalt:						
Native ... do	459, 848	3, 066, 844	490, 665	2, 725, 337	691, 168	3, 169, 193
Oil (including road oil) [8] ... do	4, 860, 540	[8] 36, 038, 696	5, 262, 959	[8] 41, 398, 735	([2, 8])	([2, 8])
Barite (crude) ... do	383, 609	2, 344, 103	409, 353	2, 596, 743	503, 156	3, 134, 234
Boron minerals ... do	245, 284	5, 689, 797	243, 355	5, 643, 390	301, 282	8, 455, 422
Bromine ... pounds	37, 882, 005	7, 611, 400	59, 266, 275	11, 772, 515	68, 317, 019	11, 506, 213
Calcium-magnesium chloride (75 percent $NaCl_2$) ... short tons	108, 441	1, 307, 717	99, 536	998, 241	165, 932	1, 333, 370
Cement ... barrels (376 pounds net)	125, 056, 594	184, 254, 932	132, 864, 383	193, 464, 869	170, 365, 440	250, 589, 481
Clay:						
Products (other than pottery and refractories) [16]		122, 528, 069		114, 000, 000		([16])
Raw (sold by producers) ... short tons	3, 760, 694	15, 354, 918	4, 700, 951	18, 162, 485	7, 018, 056	25, 193, 893
Coal:						
Bituminous [17] ... do	[18] 394, 855, 325	[18] 728, 348, 366	[19] 460, 771, 500	[19] 879, 327, 227	[19] 511, 290, 000	[19] 1, 083, 935, 000
Pennsylvania anthracite ... do	51, 487, 377	187, 175, 000	51, 484, 640	205, 490, 000	56, 368, 267	240, 275, 000
Coke [8] ... do	44, 326, 641	[8] 212, 884, 050	57, 072, 134	[8] 273, 832, 410	65, 186, 578	[8] 352, 967, 237
Diatomite ... do	([20])	([20])	([20])	([20])	([20])	([20])
Emery ... do	765	6, 828	1, 046	9, 349	4, 876	42, 484
Feldspar (crude) ... long tons	253, 466	1, 112, 857	290, 763	1, 271, 995	338, 860	1, 519, 456
Fluorspar ... short tons	182, 771	3, 704, 959	233, 600	4, 744, 808	320, 669	6, 724, 782
Fuller's earth ... do	167, 070	1, 691, 855	146, 568	1, 471, 083	207, 446	2, 111, 674
Garnet for abrasive purposes ... do	4, 056	278, 534	4, 716	259, 345	5, 501	371, 752
Gems and precious stones		([21])		([21])		([21])
Graphite:						
Amorphous ... short tons	([20])	([20])	([20])	([20])	([2, 15])	([2, 15])
Crystalline ... pounds	([20])	([20])			([2, 15])	([2, 15])

Grindstones and pulpstones ... short tons	10,434	426,375	13,323	496,448	15,536	545,556
Gypsum (crude) ... do	3,226,737	4,431,005	3,699,015	5,227,910	4,788,534	6,704,228
Helium ... cubic feet	[22] 6,281,800	[22] 75,262	[22] 9,450,855	[22] 85,061	([20])	([20])
Iodine ... pounds	([20])	([20])	([20])	([20])	([20])	([20])
Kyanite ... short tons	2,950	69,000	4,241	93,716	8,335	175,581
Lime ... do	4,254,348	30,049,394	4,886,929	33,956,385	6,079,416	42,941,162
Lithium minerals ... do	1,990	97,000	2,011	80,679	3,832	115,718
Magnesite (crude) ... do	198,980	1,465,190	333,166	2,487,969	374,799	2,655,547
Magnesium salts (natural) (including brucite) ... pounds	171,508,000	2,159,019	216,532,000	2,452,814	274,714,000	3,587,784
Marl:						
Calcareous ... short tons	22,114	38,492	25,516	42,481	183,009	175,393
Greensand ... do	6,466	318,550	6,697	389,888	11,120	619,664
Mica:						
Scrap ... do	24,672	311,895	22,386	314,565	([3] [15])	([3] [15])
Sheet ... pounds	813,708	138,963	1,625,437	291,685	([3] [15])	([3] [15])
Millstones	...	11,084	...	6,558	...	15,579
Mineral paints.						
Natural pigments [23] ... short tons	([23])	([23])	([23])	([23])	([23])	([23])
Zinc and lead pigments [24] ... do	162,774	19,029,802	164,775	19,334,347	228,123	27,994,694
Mineral waters ... gallons sold	([21])	([21])	([21])	([21])	([21])	([21])
Natural gas ... M cubic feet	2,476,756,000	534,240,000	2,660,222,000	577,939,000	2,770,000,000	608,000,000
Natural gasoline ... gallons	2,169,300,000	90,050,000	2,339,400,000	68,261,000	2,696,568,000	126,700,000
Oilstones, etc ... short tons	620	115,805	([20])	([20])	([20])	([20])
Olivine ... do	3,000	15,000	2,500	15,000	4,828	24,401
Peat ... do	55,483	362,066	70,097	516,865	86,503	657,556
Petroleum ... barrels (42 gallons)	1,264,962,000	1,294,470,000	1,353,214,000	1,385,440,000	1,404,182,000	1,570,000,000
Phosphate rock ... long tons	3,757,067	12,294,042	4,002,700	12,334,662	4,688,312	15,587,738
Potassium salts ... short tons	[25] 366,287	12,028,195	[25] 393,058	12,562,050	[25] 531,346	17,368,237
Pumice ... do	89,159	424,780	82,407	449,914	117,310	669,514
Pyrites ... long tons	519,497	1,560,000	626,640	1,920,000	659,498	2,035,000
Salt (sodium chloride) ... short tons	9,277,911	24,509,680	10,359,960	26,474,619	12,720,629	33,620,376
Sand and gravel:						
Glass sand ... do	2,468,290	4,280,936	2,759,544	4,881,508	3,475,111	6,113,529
Sand (molding, building, etc.) and gravel ... do	223,540,000	101,785,000	235,548,000	105,806,000	285,240,000	141,093,000
Sand-lime brick [26] ... thousands of brick	153,280	1,587,859	104,519	1,174,044	([26])	([26])
Silica (quartz) ... short tons	34,959	153,038	31,865	176,390	41,685	228,587
Slate ... do	531,380	6,682,214	473,450	5,738,269	618,660	7,515,634
Sodium salts (carbonates and sulfates) (natural) ... do	262,222	2,556,686	317,267	3,157,916	304,201	3,266,123
Stone [27] ... do	147,447,130	158,461,515	153,733,040	160,044,115	183,107,960	195,337,426
Sulfur ... long tons	2,233,817	35,500,000	2,558,742	40,900,000	3,401,410	54,400,000
Sulfuric acid (60° Baumé) (byproduct) [28] ... short tons	778,441	6,213,027	840,937	6,797,421	915,989	7,201,161
Talc, pyrophyllite, and ground soapstone [27] ... do	253,976	2,700,834	281,375	3,008,320	416,369	4,701,892
Tripoli ... do	33,474	466,380	30,212	366,569	29,301	421,746
Vermiculite ... do	21,174	174,587	22,299	137,698	23,438	125,444
Other nonmetallic [29]	...	2,363,251	...	2,806,861	...	4,457,215
Total value of nonmetallic products (approximate)	...	3,622,500,000	...	3,935,300,000	...	4,680,200,000

See footnotes at end of table.

Mineral products of the United States, 1939–41—Continued

Product	1939 Quantity	1939 Value	1940 Quantity	1940 Value	1941 Quantity	1941 Value
SUMMARY						
Total value:						
Metallic		$1,291,700,000		$1,679,500,000		$2,137,100,000
Nonmetallic:						
Fuels		2,834,300,000		3,116,500,000		3,628,900,000
Other		788,200,000		818,800,000		1,051,300,000
Grand total approximate value of mineral products		4,914,200,000		5,614,800,000		6,817,300,000

1 In this general statement certain of the figures represent shipments rather than quantity mined, and some of the figures for 1941 are subject to revision. For details see following chapters of this volume.
2 Figures withheld from publication at request of Committee for War Information.
3 Value included in total value of metallic products
4 Figures represent antimonial lead produced at primary refineries from both domestic and foreign primary and secondary sources, no figures for value of antimonial lead available. Estimate of value of primary antimony and lead contents of antimonial lead from domestic sources included in total value of metallic products.
5 Largely from foreign ore; value not included in total value.
6 Product from domestic ores only.
7 According to Bureau of the Mint. Valued at $35 per ounce.
8 Value not included in total value
9 Value included in total value of metallic products, Bureau of Mines not at liberty to publish figures.
10 Value calculated at nominal price—27 cents per pound.
11 Figures not available.
12 Figures showing values not available
13 According to Bureau of the Mint.
14 Includes value of following products Figures are shown wherever Bureau of Mines is at liberty to publish them.
1939: Bismuth and iron ore sold for paint (12,235 long tons, $66,817).
1940. Bismuth, cobalt oxide, and iron ore sold for paint (8,912 long tons, $45,578).
1941: Bismuth, cobalt ore, indium, iron ore sold for paint (20,792 long tons, $101,710), and zircon concentrates (174 short tons, $5,153).
15 Value included in total value of nonmetallic products.
16 Figures obtained through cooperation with Bureau of the Census Total for 1940 is estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete. Figures for 1941 not yet available; estimate of value included in total value of nonmetallic products.
17 Includes brown coal and lignite, and anthracite mined elsewhere than in Pennsylvania.
18 According to Bituminous Coal Division and Bureau of the Census; producers were asked to exclude selling expenses in reporting value, but a number of them included such expenses.
19 According to Bituminous Coal Division; value for bituminous includes selling expenses Figures for 1941 are preliminary.
20 Value included in total value of nonmetallic products, Bureau of Mines not at liberty to publish figures.
21 No canvass Estimate of value included in total value of nonmetallic products.
22 Figures cover fiscal year ended June 30 of year stated
23 Canvass discontinued after 1915 Figures for iron ore sold for paint given in footnote 14.
24 Sublimed blue lead, sublimed white lead, lead zinc oxide, and zinc oxide.
25 Equivalent as K_2O.
26 Figures obtained through cooperation with Bureau of the Census. Figures for 1941 not yet available; estimate of value included in total value of nonmetallic products.
27 Figures for soapstone used as dimension stone included in figures for stone.
28 From copper and zinc smelters and zinc roasters and from roasting of high-sulfide gold and silver concentrates.
29 Includes value of following products. Figures are shown wherever Bureau of Mines is at liberty to publish them.
1939: Andalusite, aplite, natural sulfonated bitumen, calcite (Iceland spar), chats (2,237,200 short tons, $294,200), dumortierite, flint lining for tube mills, optical fluorspar (undetermined quantity, $25), pebbles for grinding, silica sand and sandstone (ground) (310,512 short tons, $1,930,301), and sulfur ore (79 long tons, $743)
1940: Andalusite, aplite, natural sulfonated bitumen, chats (3,786,906 short tons, $572,739), dumortierite, flint lining for tube mills, pebbles for grinding, silica sand and sandstone (ground) (342,218 short tons, $2,088,314), strontium minerals, and sulfur ore (280 long tons, $3,203)
1941 Andalusite, aplite, natural sulfonated bitumen, chats (5,291,491 short tons, $897,940), dumortierite, flint lining for tube mills (3,411 short tons, $54,216), pebbles for grinding (13,561 short tons, $221,826), silica sand and sandstone (ground) (487,665 short tons, $3,073,730), strontium minerals (4,724 short tons, $69,054), and sulfur ore (409 long tons, $2,553).

Value of mineral products of the United States, 1880–1941 [1]

Year	Metallic	Nonmetallic			Grand total
		Fuels [2]	Other	Total	
1880 [1]	$190,881,000	$120,241,000	$56,341,000	$176,582,000	$367,463,000
1881	192,663,000	149,798,000	60,659,000	210,457,000	403,120,000
1882	219,070,000	170,470,000	63,557,000	234,036,000	453,106,000
1883	201,131,000	185,760,000	61,170,000	246,930,000	448,061,000

Grand total	48,519,127,000	87,534,352,000	29,740,410,000	117,274,762,000	165,823,889,000

[1] Figures for earlier years not available.
[2] Coal, natural gas, natural gasoline, petroleum.
[3] Subject to revision.

The sum of the following State totals does not reach the total for the United States given in the preceding table partly because figures for certain of the products included in the United States total are not available by States of origin. This fact is brought out in the opening text of this chapter and in the second table following.

In addition, there are many factors (the more important discussed in the opening text) that account for the disagreement between the sum of the State totals and the grand total for the United States, by products. Chief among these are: (1) The use of iron ore values in State totals and pig iron values in United States total; (2) the use of mine figures for gold, silver, copper, lead, and zinc in the State totals and mint and smelter figures (supplemented by the value of byproduct sulfuric acid from copper and zinc smelting and zinc roasting and the value of zinc and lead pigments made in large part direct from ores) in the United States total; and (3) the inclusion of estimates in the United States total for a few products for which no canvass has been conducted for many years and for which no estimate by States is made.

Many other less important differences are involved, but both State and United States totals are as complete and definite as seems possible with the data available. The practice is consistent from year to year, and it is believed that the reader can determine readily just what minerals are covered by the total concerned.

In every table each mineral produced is listed, and all figures are shown except those that the Bureau of Mines is not at liberty to publish.

Value of mineral products of the United States, 1936–40, by States [1]

State	1936	1937	1938	1939	1940
Alabama	$44, 752, 688	$53, 518, 993	$46, 296, 293	$52, 158, 173	$64, 998, 018

[1] In this table iron ore, not pig iron, is taken as the basis of iron valuation, and for other metals mine production (recoverable content of metals) is the basis. State totals for 1941 not yet available.

Mineral products of the United States and principal producing States in 1940

Rank in value	Product	Principal producing States [1]: In order of quantity	Principal producing States [1]: In order of value
14	Aluminum	New York, Tennessee, North Carolina, Washington	Rank same as for quantity.
91	Andalusite	Nevada	Do.
(²)	Antimonial lead	Not separable by States	Not separable by States.
81	Antimony ore	Nevada, Idaho, Alaska, California	Alaska, Nevada, Idaho, California.
82	Aplite	Virginia	Rank same as for quantity.
62	Arsenious oxide	Montana, Utah	Do.
58	Asbestos	Vermont, Arizona, Georgia, North Carolina	Do.
	Asphalt:		
41	Native	Texas, Oklahoma, Kentucky, Alabama	Kentucky, Utah, Oklahoma, Texas.
19	Oil	Not separable by States	Not separable by States.
42	Barite (crude)	Missouri, Georgia, Tennessee California	Missouri, Tennessee, Georgia, California.
43	Bauxite	Arkansas, Alabama, Georgia, Virginia	Rank same as for quantity.
94	Beryllium ore (beryl)	South Dakota, Colorado, Maine	Do.
55	Bismuth	Not separable by States	Not separable by States.
97	Bitumen (natural sulfonated)	Utah	Rank same as for quantity.
34	Boron minerals	California	Do.
28	Bromine	North Carolina, Michigan, California, West Virginia	Do.
37	Cadmium	Not separable by States	Not separable by States.
57	Calcium-magnesium chloride	Michigan, West Virginia, California, Ohio	Rank same as for quantity.
8	Cement	Pennsylvania, California, New York, Michigan	Pennsylvania, California, New York, Texas.
60	Chats	Oklahoma, Missouri, Kansas	Rank same as for quantity.
87	Chromite	California, Oregon	Do.
	Clay:		
12	Products (other than pottery and refractories).		Ohio, Pennsylvania, California, Illinois.
24	Raw (sold by producers)	Pennsylvania, Georgia, Ohio, Missouri	Georgia, Pennsylvania, Missouri, Kentucky.
2	Coal:		
	Bituminous	West Virginia, Pennsylvania, Illinois, Kentucky	Pennsylvania, West Virginia, Kentucky, Illinois.
	Pennsylvania anthracite	Pennsylvania	Rank same as for quantity.
84	Cobalt oxide	do	Do.
5	Coke	Pennsylvania, Ohio, Indiana, New York	Do.
7	Copper	Arizona, Utah, Montana, Nevada	Do.
49	Diatomite	California, Washington, Oregon, Nevada	California, Washington, Oregon, Florida.
96	Dumortierite	Nevada	Rank same as for quantity.
90	Emery	New York	Do.
51	Feldspar (crude)	North Carolina, South Dakota, New Hampshire, Colorado	North Carolina, South Dakota, New Hampshire, Connecticut.
11	Ferro-alloys	Pennsylvania, New York, Ohio, West Virginia	Pennsylvania, New York, West Virginia, Ohio.
92	Flint lining for tube mills	Minnesota	Rank same as for quantity.
36	Fluorspar	Illinois, Kentucky, Colorado, New Mexico	Do.
50	Fuller's earth	Georgia, Texas, Florida, Illinois	Georgia, Florida, Texas, Illinois.
72	Garnet (abrasive)	New York, Vermont, North Carolina, Idaho	Rank same as for quantity.
(³)	Gems and precious stones	No canvass for 1940	No canvass for 1940.
6	Gold	California, Alaska, South Dakota, Nevada	Rank same as for quantity.

98	Graphite: Amorphous	Nevada	Do.
64	Grindstones and pulpstones	Ohio, West Virginia, Washington	Do.
35	Gypsum (crude)	New York, Michigan, Iowa, Texas	New York, Michigan, Nevada, Iowa.
79	Helium	Texas	Rank same as for quantity.
65	Iodine (natural)	California	Do.
	Iron.		
9	Ore	Minnesota, Michigan, Alabama, Pennsylvania	Do.
3	Pig	Pennsylvania, Ohio, Indiana, Illinois	Do
54	Sinter	Tennessee	Do.
78	Kyanite	California, Virginia, Georgia, North Carolina	Do.
18	Lead	Missouri, Idaho, Utah, Montana	Do.
21	Lime	Ohio, Pennsylvania, Missouri, West Virginia	Do.
80	Lithium minerals	South Dakota, California, North Carolina	California, South Dakota, North Carolina.
44	Magnesite (crude)	Washington, California, Texas, Nevada	Washington, California, Nevada, Texas.
38	Magnesium	Michigan	Rank same as for quantity.
45	Magnesium salts (natural)	Michigan, Nevada, California, Washington	Michigan, California, Nevada, Washington.
53	Manganese ore	Montana, Tennessee, Arkansas, Georgia	Montana, Arkansas, Tennessee, Georgia.
39	Manganiferous ore	Minnesota, New Mexico, Michigan, Georgia	Minnesota, New Mexico, Georgia, Montana.
69	Manganiferous zinc residuum	New Jersey	Rank same as for quantity.
	Marl:		
85	Calcareous	Virginia, Wisconsin, West Virginia, Nevada	West Virginia, Wisconsin, Virginia, Nevada.
68	Greensand	New Jersey	Rank same as for quantity.
31	Mercury	California, Oregon, Nevada, Arkansas	Do.
59	Mica	North Carolina, Virginia, South Dakota, Colorado	North Carolina, Connecticut, South Dakota, Virginia.
	Scrap	do	North Carolina, Virginia, Georgia, South Dakota.
	Sheet	North Carolina, Connecticut, New Hampshire, South Dakota	Rank same as for quantity.
93	Millstones		North Carolina, Virginia, New York.
23	Mineral paints (zinc and lead pigments)	Pennsylvania, Illinois, Kansas, Indiana	Rank same as for quantity.
([3])	Mineral waters	No canvass for 1940	No canvass for 1940.
25	Molybdenum	Colorado, Utah, New Mexico, Arizona	Rank same as for quantity.
4	Natural gas	Texas, California, Louisiana, Oklahoma	Texas, California, West Virginia, Louisiana.
16	Natural gasoline	Texas, California, Oklahoma Louisiana	California, Texas, Oklahoma, Louisiana.
71	Nickel	Not separable by States	Not separable by States.
77	Oilstones, etc	Arkansas, Ohio, New Hampshire, Indiana	Rank same as for quantity.
89	Olivine	North Carolina	Do.
([4])	Ores (crude), etc.:		
	Copper	Utah, Arizona, New Mexico, Nevada	Value not available.
	Dry and siliceous (gold and silver)	Alaska, California, Nevada, South Dakota	Do.
	Lead	Missouri, Idaho, Utah, Montana	Do.
	Lead-copper	Utah, Colorado, Idaho, Montana	Do.
	Zinc	Oklahoma, Tennessee, Kansas, New Jersey	Do.
	Zinc-copper	Arizona	Do.
	Zinc-lead	Oklahoma, Kansas, Idaho, Utah	Do.
	Zinc-lead-copper	Utah	Do.
63	Peat	New York, New Jersey, Pennsylvania, Maine	New York, Maine, New Jersey, Michigan.
88	Pebbles for grinding	Minnesota, North Carolina, California	Rank same as for quantity.
1	Petroleum	Texas, California, Oklahoma, Illinois	Do.
27	Phosphate rock	Florida, Tennessee, Idaho, Montana	Do.
47	Platinum metals	Alaska, California, Oregon, Montana	Do.
26	Potassium salts	New Mexico, California, Utah, Maryland	Do.
66	Pumice	Kansas, California, Nebraska, New Mexico	California, Kansas, New Mexico, Nebraska.

See footnotes at end of table.

Mineral products of the United States and principal producing States in 1940—Continued

Rank in value	Product	Principal producing States: In order of quantity	Principal producing States: In order of value
48	Pyrites	Tennessee, Virginia, California, New York	Rank same as for quantity.
22	Salt	Michigan, New York, Ohio, Louisiana	Michigan, New York, Louisiana, Ohio.
13	Sand and gravel	California, New York, Michigan, Illinois	California, Pennsylvania, New York, Ohio.
52	Sand-lime brick	New York, New Jersey, Michigan, Minnesota	New York, Michigan, New Jersey, Massachusetts.
61	Selenium	Not separable by States	Not separable by States
74	Silica (quartz)	Wisconsin, New Jersey, North Carolina, Tennessee	New Jersey, Wisconsin, North Carolina, California
46	Silica sand and sandstone (ground)	Illinois, New Jersey, West Virginia, Ohio	Illinois, New Jersey, Ohio, West Virginia.
17	Silver	Idaho, Montana, Utah, Colorado	Rank same as for quantity.
33	Slate		Pennsylvania, Vermont, New York, Virginia.
29	Sodium salts (other than NaCl) (natural)	California, Texas, Utah, Wyoming	Rank same as for quantity.
10	Stone	Pennsylvania, Michigan, Ohio, New York	Pennsylvania, New York, Ohio, Illinois.
86	Strontium minerals	Texas, California, Washington, Ohio	Rank same as for quantity.
20	Sulfur	Texas, Louisiana, California, Utah	Do.
30	Sulfuric acid from copper and zinc smelters and roasters and from roasting of high-sulfide gold and silver concentrates.	Pennsylvania, Illinois, Tennessee, Arizona	Pennsylvania, Illinois, Tennessee, Oklahoma.
95	Sulfur ore	Texas, Colorado, Nevada	Rank same as for quantity.
40	Talc, pyrophyllite, and ground soapstone [5]	New York, North Carolina, Vermont, California	New York, California, Vermont, North Carolina.
76	Tellurium	Not separable by States	Not separable by States.
83	Tin	Alaska, South Dakota, New Mexico, Montana	Rank same as for quantity.
	Titanium ore		
73	Ilmenite	Virginia, Florida	Do.
67	Rutile	Virginia, Arkansas, Florida	Do.
70	Tripoli	Missouri, Illinois, Arkansas, Oklahoma	Illinois, Missouri, Arkansas, Oklahoma.
32	Tungsten ore	California, Nevada, Colorado, Arizona	Rank same as for quantity.
56	Uranium and vanadium ores	Colorado, Utah	Do.
75	Vermiculite	Montana, North Carolina, Wyoming, Texas	Montana, North Carolina, Wyoming, Colorado
15	Zinc	Oklahoma, New Jersey, Idaho, Kansas	Rank same as for quantity.

[1] Rank of States in metal production (except aluminum, ferro-alloys, and pig iron) arranged according to mine reports, not smelter output.
[2] Separate figures for antimonial lead from primary sources not available.
[3] No canvass for 1940.
[4] Value not available.
[5] Exclusive of soapstone used as dimension stone (all from Virginia), which is included in figures for stone.

States and their principal mineral products in 1940 [1]

State	Rank	Percent of total value for United States	Principal mineral products in order of value
Alabama	18	1.39	Coal, iron ore, cement, stone.
Alaska	29	.62	Gold, platinum metals, coal, silver.
Arizona	14	1.82	Copper, gold, silver, zinc.
Arkansas	27	.80	Petroleum, coal, natural gas, bauxite.
California	3	9.75	Petroleum, natural gas, gold, natural gasoline.
Colorado	19	1.35	Coal, molybdenum, gold, silver.
Connecticut	45	.08	Stone, clay products, sand and gravel, feldspar.
Delaware	50	.01	Clay products, stone, sand and gravel, raw clay.
District of Columbia	49	.01	Clay products, stone.
Florida	35	.32	Phosphate rock, stone, cement, sand and gravel.
Georgia	34	.36	Stone, raw clay, clay products, cement.
Idaho	26	.87	Silver, lead, zinc, gold.
Illinois	5	5.95	Petroleum, coal, stone, cement
Indiana	20	1.26	Coal, cement, stone, petroleum
Iowa	31	.56	Coal, cement, stone, clay products
Kansas	9	2.80	Petroleum, natural gas, zinc, coal.
Kentucky	8	2.82	Coal, natural gas, petroleum, stone
Louisiana	7	4.05	Petroleum, natural gas, sulfur, salt
Maine	44	.09	Stone, sand and gravel, cement, clay products
Maryland	37	.27	Coal, sand and gravel, cement, clay products.
Massachusetts	39	.16	Stone, sand and gravel, clay products, lime.
Michigan	12	2.67	Iron ore, petroleum, cement, copper.
Minnesota	11	2.75	Iron ore, manganiferous ore, stone, sand and gravel.
Mississippi	40	.16	Petroleum, natural gas, clay products, sand and gravel.
Missouri	21	1.08	Lead, cement, coal, stone
Montana	16	1.70	Copper, gold, silver natural gas.
Nebraska	43	.10	Cement, sand and gravel, stone, clay products
Nevada	25	.91	Copper, gold, silver, tungsten ore
New Hampshire	47	.02	Stone, sand and gravel, clay products, feldspar.
New Jersey	28	.72	Zinc, clay products, sand and gravel, iron ore.
New Mexico	15	1.73	Petroleum, copper, natural gas, potassium salts.
New York	17	1.63	Cement, petroleum, stone, natural gas
North Carolina	33	.45	Bromine, stone, clay products, sand and gravel.
North Dakota	46	.06	Coal, sand and gravel, clay products, stone
Ohio	10	2.80	Coal, clay products, natural gas, stone.
Oklahoma	6	5.04	Petroleum, natural gas, zinc, natural gasoline.
Oregon	38	.24	Gold, stone, mercury, cement
Pennsylvania	2	13.23	Coal, natural gas, petroleum, cement.
Rhode Island	48	.02	Stone, sand and gravel, clay products, lime.
South Carolina	42	.11	Clay products, stone, raw clay, gold
South Dakota	32	.50	Gold, stone, cement, sand and gravel
Tennessee	24	.91	Coal, stone, cement, zinc.
Texas	1	15.51	Petroleum, natural gas, sulfur, natural gasoline.
Utah	13	2.23	Copper, gold, silver, coal.
Vermont	41	.15	Stone, slate, asbestos, lime.
Virginia	22	1.07	Coal, stone, cement, clay products.
Washington	30	.60	Cement, coal, sand and gravel, gold.
West Virginia	4	7.06	Coal, natural gas, petroleum, stone.
Wisconsin	36	.29	Stone, iron ore, sand and gravel, cement
Wyoming	23	.92	Petroleum, coal, natural gas, natural gasoline.

[1] In this table iron ore, not pig iron, is taken as the basis of iron valuation, and for other metals mine production (recoverable content of metals) is the basis.

Prices of gold, silver, copper, lead, and zinc, 1932–41 [1]

Year	Gold [2]	Silver [3]	Copper [4]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1932	[5] $20.67+	$0.282	$0.063	$0.030	$0.030
1933	25.56	.350	.064	.037	.042
1934	34.95	[6] .646+	.080	.037	.043
1935	35.00	.71875	.083	.040	.044
1936	35.00	.7745	.092	.046	.050
1937	35.00	.7735	.121	.059	.065
1938	35.00	[6] .646+	.098	.046	.048
1939	35.00	[7] .678+	.104	.047	.052
1940	35.00	[8] .711+	.113	.050	.063
1941	35.00	[8] .711+	.118	.057	.075

[1] Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+ per fine ounce. For table of prices for silver, copper, lead, and zinc from 1850 to 1931, by years, see Mineral Resources, 1931, pt. 1, p. A115.

[2] 1932: Legal coinage value; 1933–34: Yearly average weighted Government price; 1935–41: Price under authority of Gold Reserve Act of January 31, 1934.

[3] 1932–33: Average New York price for bar silver; 1934 and 1938–41: Treasury buying price for newly mined silver; 1935–37: Yearly average weighted Treasury buying price for newly mined silver

[4] Yearly average weighted price of all grades of primary metal sold by producers.

[5] $20.671835. [6] $0.64646464. [7] $0.67878787. [8] $0.71111111.

STATE TABLES

Mineral production of Alabama, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Asphalt (native)......short tons..	(1)	(1)	(1)	(1)
Barite......do....	(1)	(1)		
Bauxite......long tons..	(1)	(1)	(1)	(1)
Cement......barrels..	[2] 5,042,921	[2] $6,690,765	[2] 5,249,759	[2] $7,617,405
Clay:				
Products (other than pottery and refractories)...		[3] 2,306,712		[3] 2,394,000
Raw (sold by producers)......short tons..	51,015	83,933	144,354	143,363
Coal......do....	[4] 12,046,675	[4] 27,741,791	[5] 15,324,163	[5] 35,777,923
Coke......do....	3,854,505	[6] 10,917,559	4,727,378	[6] 13,748,837
Ferro-alloys......do....	31,440	[6] 1,802,917	45,184	[6] 3,422,111
Gold......troy ounces..	3	105	5	175
Iron.				
Ore......long tons..	5,985,208	9,971,024	7,330,412	12,606,369
Pig......short tons..	3,043,602	[6] 43,902,681	3,476,072	[6] 49,706,851
Lime......do....	176,513	1,004,785	234,147	1,359,371
Manganese ore......long tons..	187	3,742	243	(1)
Manganiferous ore......do....	519	4,561	342	(1)
Mica:				
Scrap......short tons..			(1)	(1)
Sheet......pounds..			(1)	(1)
Mineral waters......gallons sold..	(7)	(7)	(7)	(7)
Ore (dry and siliceous) (gold and silver).short tons..	10	(8)	900	(8)
Sand and gravel......do....	1,283,577	687,265	1,840,945	936,724
Silver......troy ounces..			3	2
Stone......short tons..	1,855,990	2,516,584	2,496,480	3,048,043
Miscellaneous [9]......		1,146,906		1,114,643
Total value, eliminating duplications......		52,158,173		64,998,018

[1] Value included under "Miscellaneous."
[2] Exclusive of puzzolan, value for which is included under "Miscellaneous."
[3] Figures obtained through cooperation with Bureau of the Census. Total for 1940 is estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete.
[4] According to Bituminous Coal Division and Bureau of the Census, producers were asked to exclude selling expenses in reporting value, but a number of them included such expenses.
[5] According to Bituminous Coal Division, value includes selling expenses.
[6] Value not included in total value for State.
[7] No canvass.
[8] Not valued as ore; value of recoverable metal content included under the metals.
[9] Includes minerals indicated by "1" and "2" above.

Mineral production of Alaska, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Antimony ore (concentrates)......short tons..	(1)	(1)	(1)	(1)
Arsenic......do....	(2)	(2)	(2)	(2)
Coal......do....	[3] 146,250	[3] $585,000	[3] 173,970	[3] $695,000
Copper......pounds..	256,000	26,624	110,000	12,430
Gold......troy ounces..	676,737	23,685,795	755,970	26,458,950
Lead......short tons..	937	88,078	779	77,900
Mercury......flasks (76 pounds)..			162	28,653
Ores (crude), etc.:				
Copper......short tons..	165	(4)		
Dry and siliceous (gold and silver)......do....	4,751,492	(4)	4,885,023	(4)
Platinum metals (crude)......troy ounces..	31,300	997,000	32,300	1,093,000
Sand and gravel......short tons..	[5] 42,332	[5] 23,112	515,011	103,217
Silver......troy ounces..	201,054	136,473	191,679	136,305
Stone......short tons..	(1)	(1)	(1)	(1)
Tin (metallic equivalent)......do....	37	37,300	52	52,000
Miscellaneous [6]......		94,184		66,766
Total value, eliminating duplications......		25,673,566		28,724,221

[1] Value included under "Miscellaneous."
[2] Figures not available.
[3] According to the Alaskan Branch of the Geological Survey.
[4] Not valued as ore; value of recoverable metal content included under the metals.
[5] "Government-and-contractor." Value of "Commercial" included under "Miscellaneous."
[6] Includes minerals indicated by "1" and "5" above.

Mineral production of Arizona, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Antimony ore (concentrates)...short tons..			(1)	(1)
Arsenious oxide...do....	(2)	(2)	(2)	(2)
Asbestos...do....	904	$95,807	1,197	$149,290
Barite...do....	(1)	(1)		
Bismuth...pounds..			(2)	(2)
Clay:				
Products (other than pottery and refractories)...		[3] 237,542		[3] 306,000
Raw (sold by producers)...short tons..	(1)	(1)	(1)	(1)
Coal...do....	(1, 4)	(1, 4)	(1, 5)	(1, 5)
Copper...pounds..	524,224,000	54,519,296	562,338,000	63,544,194
Feldspar (crude)...long tons..	(1)	(1)	(1)	(1)
Fluorspar...short tons..	(1)	(1)	(1)	(1)
Gems and precious stones...		(6)		(6)
Gold...troy ounces..	316,453	11,075,855	294,807	10,318,245
Gypsum (crude)...short tons..	(1)	(1)		
Lead...do....	10,771	1,012,474	13,266	1,326,600
Lime...do....	57,233	448,860	67,882	502,998

Mercury...flasks (76 pounds)..	(1)	(1)	740	130,884
Mica, scrap...short tons..	(1)	(1)	(1)	(1)
Molybdenum...pounds..	711,192	(1)	406,306	(1)
Ores (crude), etc.:				
Copper...short tons..	17,468,926	(7)	20,284,826	(7)
Dry and siliceous (gold and silver)...do....	1,042,004	(7)	928,448	(7)
Lead...do....	9,778	(7)	8,813	(7)
Lead-copper...do....	30	(7)	44	(7)
Zinc...do....	670	(7)		
Zinc-copper...do....	67,074	(7)	79,044	(7)
Zinc-lead...do....	204,778	(7)	271,000	(7)
Sand and gravel...do....	655,155	261,316	245,602	114,500
Sand-lime brick...thousands of brick..	(1, 8)	(1, 8)	(1, 8)	(1, 8)
Silica (quartz)...short tons..	(1)	(1)	(1)	(1)
Silver...troy ounces..	7,824,004	5,310,839	7,075,215	5,031,264
Stone...short tons..	665,290	626,281	1,149,000	1,043,101
Sulfuric acid [9]...do....	(1, 10)	(1, 10)	(1, 10)	(1, 10)
Tungsten ore (60-percent concentrates)...do....	100	103,980	349	471,546
Vanadium from complex ore...	(1)	(1)	(1)	(1)
Zinc...short tons..	6,711	697,944	15,456	1,947,456
Miscellaneous [11]...		1,183,915		798,684
Total value, eliminating duplications...		75,087,930		85,277,347

[1] Value included under "Miscellaneous."
[2] Figures not available.
[3] Figures obtained through cooperation with Bureau of the Census. Total for 1940 is estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete.
[4] According to Bituminous Coal Division and Bureau of the Census; producers were asked to exclude selling expenses in reporting value, but a number of them included such expenses.
[5] According to Bituminous Coal Division; value includes selling expenses.
[6] No canvass.
[7] Not valued as ore; value of recoverable metal content included under the metals
[8] Figures obtained through cooperation with Bureau of the Census.
[9] From copper smelting.
[10] Value not included in total value for State.
[11] Includes minerals indicated by "1" above.

Mineral production of Arkansas, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Barite ... short tons			(1)	(1)
Bauxite ... long tons	361, 256	$2, 074, 954	423, 283	$2, 501, 393
Cement ... barrels	(1)	(1)	(1)	(1)
Clay.				
Products (other than pottery and refractories)		[2] 944, 661		[2] 792, 780
Raw (sold by producers) ... short tons	(1)	(1)	24, 997	13, 845
Coal ... do	[3] 1, 152, 038	[3] 3, 655, 438	[4] 1, 453, 611	[4] 4, 879, 286
Gems and precious stones		(5)		(5)
Lead ... short tons			55	5, 500
Lime ... do	(1)	(1)	(1)	(1)
Manganese ore ... long tons	5, 365	(1)	6, 079	(1)
Manganiferous ore ... do	1, 970	(1)	1, 075	(1)
Mercury ... flasks (76 pounds)	364	37, 834	1, 159	204, 992

[1] Exclusive of natural cement, value for which is included under "Miscellaneous."
[2] Figures obtained through cooperation with Bureau of the Census. Total for 1940 is estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete.
[3] According to Bituminous Coal Division and Bureau of the Census; producers were asked to exclude selling expenses in reporting value, but a number of them included such expenses.
[4] According to Bituminous Coal Division; value includes selling expenses.
[5] Value not included in total value for State.
[6] Value included under "Miscellaneous."
[7] Quantity undetermined.
[8] No canvass.
[9] Not valued as ore; value of recoverable metal content included under the metals.
[10] No ore milled in northern Illinois in 1939; metal output of southern Illinois was byproduct of fluorspar milling.
[11] "Commercial" Value of "Government-and-contractor" included under "Miscellaneous."
[12] Figures obtained through cooperation with Bureau of the Census.
[13] Exclusive of unclassified stone, value for which is included under "Miscellaneous."
[14] From zinc smelting.
[15] Includes minerals indicated by "1", "6", "11", and "13" above.

Mineral production of Indiana, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Cement ... barrels	(1)	(1)	(1)	(1)
Clay:				
Products (other than pottery and refractories)		[2] $5,629,014		[2] $4,265,000

[8] "Commercial." Value of "Government-and-contractor" included under "Miscellaneous."
[9] Exclusive of sandstone, value for which is included under "Miscellaneous."
[10] Includes minerals indicated by "2," "8," and "9" above.

Mineral production of Pennsylvania, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Asbestos……short tons			(1)	(1)
Cement……barrels	[2] 24,870,343	[2] $34,332,649	[2] 27,499,786	[2] $38,350,998
Clay:				
Products (other than pottery and refractories)		[3] 11,351,849		[3] 11,031,000
Raw (sold by producers)……short tons	667,140	1,675,019	899,173	2,189,509
Coal:				
Anthracite……do	51,487,377	187,175,000	51,484,640	205,490,000
Bituminous……do	[4] 92,584,113	[4] 187,609,657	[5] 116,602,999	[5] 237,333,374
Cobalt oxide……pounds			(1)	(1)
Coke……short tons	12,120,225	[6] 49,015,558	17,412,024	[6] 69,599,076
Copper [7]……pounds	(1)	(1)	(1)	(1)
Feldspar (crude)……long tons	(1)	(1)	(1)	(1)
Ferro-alloys……short tons	322,647	[6] 29,609,712	512,174	[6] 56,983,213
Gems and precious stones		(8)		(8)
Gold [7]……troy ounces	1,815	63,525	1,840	64,400
Iron:				
Ore—				
Sold to furnaces……long tons	(1)	(1)	(1)	(1)
Sold for paint……do	463	(1)	(1)	(1)
Pig……short tons	10,057,207	[6] 186,302,533	14,571,517	[6] 282,666,561
Lime……do	691,460	4,744,197	833,038	5,622,725
Mineral paints (zinc and lead pigments)……do	(1 6)	(1 6)	(1 6)	(1 6)
Mineral waters……gallons sold	(8)	(8)	(8)	(8)
Natural gas……M cubic feet	93,882,000	35,268,000	90,725,000	41,733,000
Natural gasoline……gallons	11,756,000	499,000	15,371,000	594,000
Peat……short tons	(1)	(1)	8,310	23,540
Petroleum……barrels	17,382,000	36,200,000	17,353,000	39,700,000
Pyrites……long tons	(1)	(1)	(1)	(1)
Sand and gravel……short tons	6,779,592	6,752,222	8,431,656	8,000,225
Sand and sandstone (ground)……do	(1)	(1)	(1)	(1)
Sand-lime brick……thousands of brick	(1 9)	(1 9)	(1 9)	(1 9)
Silica (quartz)……short tons			(1)	(1)
Silver [7]……troy ounces	13,558	9,203	13,064	9,290
Slate		3,056,853		2,609,801
Soapstone……short tons	(1)	(1)	(1)	(1)
Stone……do	[10] 15,743,790	[10] 16,906,854	[10] 19,277,690	[10] 19,855,478
Sulfuric acid (60° Baumé) [11]……do	254,758	[6] 2,295,370	299,751	[6] 2,739,724
Tripoli (rottenstone)……do	(1)	(1)	(1)	(1)
Miscellaneous [12]		14,660,980		15,290,396
Total value, eliminating duplications		531,007,890		618,347,805

1 Value included under "Miscellaneous."
2 Exclusive of natural cement, value for which is included under "Miscellaneous."
3 Figures obtained through cooperation with Bureau of the Census. Total for 1940 is estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete.
4 According to Bituminous Coal Division and Bureau of the Census; producers were asked to exclude selling expenses in reporting value, but a number of them included such expenses.
5 According to Bituminous Coal Division; value includes selling expenses.
6 Value not included in total value for State.
7 Copper, gold, and silver were recovered from magnetite-pyrite-chalcopyrite ore, which is included as iron ore produced. Bureau of Mines not at liberty to publish figures.
8 No canvass.
9 Figures obtained through cooperation with Bureau of the Census.
10 Exclusive of dimension basalt, value for which is included under "Miscellaneous."
11 From zinc smelting.
12 Includes minerals indicated by "1," "2," and "10" above.

Mineral production of Rhode Island, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Clay products (other than pottery and refractories)		(1 2)		(1 2)
Coke short tons	(1 3)	(1 3)	(1 3)	(1 3)
Lime do	(1)	(1)	(1)	(1)
Mineral waters gallons sold	(4)	(4)	(4)	(4)
Sand and gravel short tons	383,557	$265,631	515,129	$333,612
Stone do	320,780	558,944	[5] 201,380	[5] 511,620
Miscellaneous [6]		1,690,297		1,960,840
Total value, eliminating duplications		980,916		994,997

[1] Value included under "Miscellaneous."
[2] Figures obtained through cooperation with Bureau of the Census.
[3] Value not included in total value for State.
[4] No canvass
[5] Exclusive of dimension basalt, value for which is included under "Miscellaneous."
[6] Includes minerals indicated by "1" and "5" above.

Mineral production of South Carolina, 1939–40

Product	1939		1940	
	Quantity	Value	Quantity	Value
Asbestos short tons	(1)	(1)		
Barite do	(1)	(1)	(1)	(1)
Clay:				
Products (other than pottery and refractories)		[2] $1,573,470		[2] $1,688,000
Raw (sold by producers) short tons	159,164	1,303,163	152,529	1,306,438

Miscellaneous [11].....	.....	9,355,393	.....	10,431,709
Total value, eliminating duplications.....	.....	80,127,521	.....	104,392,989

[1] Value included under "Miscellaneous."
[2] Figures not available.
[3] Figures obtained through cooperation with Bureau of the Census.
[4] According to Bituminous Coal Division and Bureau of the Census; producers were asked to exclude selling expenses in reporting value, but a number of them included such expenses.
[5] According to Bituminous Coal Division; value includes selling expenses.
[6] Value not included in total value for State.
[7] No canvass.
[8] Not valued as ore; value of recoverable metal content included under the metals.
[9] Exclusive of granite, value for which is included under "Miscellaneous."
[10] From copper smelting.
[11] Includes minerals indicated by "1" and "9" above.

Mineral production of Vermont, 1939–40

Product	1939 Quantity	1939 Value	1940 Quantity	1940 Value
Asbestos short tons	(1)	(1)	(1)	(1)
Clay:				
Products (other than pottery and refractories)		(1 2)		(1 2)
Raw (sold by producers) short tons	(1)	(1)	(1)	(1)

PART II. METALS

GOLD AND SILVER

By CHAS. W. HENDERSON AND C. E. NEEDHAM

SUMMARY OUTLINE

SUMMARY

Gold and silver in 1941 failed to maintain the high rate of production set by the industry in 1940, which was a record year in many countries. World output of gold dropped an estimated 4 percent. Most of the slump is attributed to Europe; however, no reliable data have been obtained either on gold or silver from any of the European countries, and this is true as well for nearly all of the Asiatic nations and most of those in Africa and Oceania. World production of silver is estimated to have dropped nearly 3 percent, most of which represents reduced output in Canada, Mexico, and Peru.

Output of gold in North America dropped less than 1 percent in 1941. Although production in the United States decreased nearly 1 percent, increases were appreciable in Canada and Nicaragua. Silver made a poorer showing and dropped nearly 3 percent.

Among the gold-producing countries of the world, the Union of South Africa, with an output of more than 14,000,000 ounces, continued well in the lead and produced about 35 percent of total world output in 1941. The Union succeeded in increasing its output by 2½ percent in spite of losses of skilled workmen and engineers to military service, conversion of workshops to munition work, difficulty in obtaining steel, and increased working costs. This favorable showing was accomplished by extending the ordinary working hours, by amending leave arrangements, by working overtime, by practicing the strictest economy in the use of all stores, by using substitute materials wherever possible, by reducing replacements in equipment to a minimum, and by the restriction of development work.

In the United States less attention was given to gold and silver and more to base metals in order to meet the great demands of the war program. Early in 1942, the War Production Board asked gold and silver operators to give precedence to more essential operations to conserve mining material and supplies, and gold and silver mines were excluded from the priority benefits of Preference Rating Order P-56. This exclusion caused considerable disturbance and misunderstanding in the industry, and protests followed. In a short time it was stated that the case of each mine would be reviewed and if the mine was found to produce needed amounts of copper, lead, or zinc, its serial number would be reinstated.

Gold and silver producers in the Latin American countries faced an increasing shortage of mine and mill machinery, most of which comes from the United States. Moreover, their operations were handicapped by inadequate shipping facilities for their ores and concentrates to United States smelters. Naturally, it is expected that production will decrease still more in 1942.

Although gold and silver had been considered quite unessential to the war effort, late in 1941 they began to make many important contributions to industry. This applied especially to silver, of which surprising amounts were used in the war industries by 1942. A more detailed discussion in this connection is given later in this chapter.

DOMESTIC REFINERY PRODUCTION

The figures in the following table were obtained through cooperation between the United States Bureau of the Mint and the Bureau of Mines and were agreed upon after conference and adjustment between the two Bureaus.

The State totals are based upon bullion deposits in the United States mints and assay offices and upon returns to the Bureau of the Mint from smelting and refining companies. The State distribution is adjusted further by the Bureau of Mines from its geographical records of sources and production, both historical and current, from the producing mines and is tabulated for the mine reports discussed later. The data for the total production and in part for the distribution are obtained from records of (1) the unrefined domestic gold and silver deposited in the United States mints and assay offices; (2) the domestic gold and silver in fine bars reported by private refineries, supplemented by data of content of unrefined mattes, blister copper, copper anodes, and lead bullion; and (3) the unrefined domestic gold and silver contained in ore and matte exported for reduction. The last item is small.

Gold and silver produced in the United States, 1937–41, and approximate distribution of source, by States and Territories, in 1941

[Refinery figures supplied by U. S. Bureau of the Mint]

State or Territory	Gold[1]		Silver[2]

[1] Gold valued at $35 a fine ounce.
[2] Silver valued as follows 1937, $0.7735, 1938, $0.646+; 1939, $0.678787+; 1940 and 1941, $0.7111+.

Gold and silver produced in the United States, 1792–1941

[From Report of the Director of the Mint. The estimate for 1792-1873 is by R. W. Raymond, commissioner of mining statistics, and since then by the Director of the Mint]

Period	Gold		Silver	
	Fine ounces	Value[1]	Fine ounces	Value[2]
1792-1847	1,187,170	$24,537,000	309,500	$404,500
1848-72	58,279,778	1,204,750,000	118,568,200	157,749,900
1873-1941	207,958,229	4,851,125,300	3,610,431,694	2,715,323,848
	267,425,177	6,080,412,300	3,729,309,394	2,873,478,248

[1] Gold valued in 1934 and thereafter at $35 per fine ounce; prior thereto at $20.67+ per fine ounce. Dollar figures are rounded.
[2] Silver valued in 1934 and thereafter at Government's average buying price for domestic product: In 1934 and 1938 at $0.64+ per fine ounce, in 1935 at $0.71875, in 1936 at $0.7745, in 1937 at $0.7735, in 1939 at $0.678787+, and in 1940 and 1941 at $0.7111+.

The average commercial value per fine ounce of silver for the total recorded domestic production is $0.771.

PRICES OF GOLD AND SILVER

Gold.—Under the Gold Reserve Act of 1934 the value of gold was fixed by Presidential proclamation on January 31, 1934, at $35 per fine troy ounce and has remained at that figure through 1941. From January 18, 1837,[1] through 1932, the price was $20.67+ per ounce, and in 1933 the legal coinage value was continued at $20.67+. The average weighted price per fine ounce in 1933, as computed by the Bureau of Mines, was $25.56 and in 1934, $34.95. A complete account of regulations pertaining to gold and silver in 1933–34 is given in the chapter on Gold and Silver in Minerals Yearbook, 1934 (pp. 25–46), issued by the Bureau of Mines.

Silver.—The Government price for newly mined domestic silver was maintained throughout 1938 and to June 30, 1939, at $0.646464646+ per fine ounce. The act of Congress approved July 6, 1939, fixed the price of domestic silver mined after July 1, 1939, at $0.711+ per ounce. The annual average prices [2] used for domestic silver from 1932 to 1939 are as follows: 1932, $0.282; 1933, $0.350; 1934, $0.646464646+; 1935, $0.71875; 1936, $0.7745; 1937, $0.7735; 1938, $0.646464646+; 1939, $0.678787878+; 1940–41, $0.711111111+.

The following table, copied from the Annual Report of the Director of the Mint for the Fiscal Year Ended June 30, 1941, shows the price of silver in London and in New York in 1940 and the first half of 1941.

Price of silver in London and in New York, 1940–41

[2] For highest, lowest, and average price of silver in New York, 1874–1935, see Minerals Yearbook, 1937, p. 115; for ratio of silver to gold, 1687–1935, p. 121.

UNITED STATES AND WORLD MONETARY STOCKS

According to figures published in the Federal Reserve Bulletin, the gold reserves of the United States increased $742,000,000 in 1941 and totaled $22,737,000,000 at the end of the year. The gain in 1941 was the smallest since the year before the legal value of gold was raised from $20.67+ to $35 a fine ounce. The record gain of $4,351,000,000 occurred in 1940, when much gold was acquired from European countries invaded by Germany. During the first 5 months of 1942 the gold reserves decreased slightly and were shown by the daily statement of the United States Treasury, June 8, 1942, to be 649,033,271.8 fine ounces valued at $22,716,164,513.90.

Figures on gold reserves held by central banks and governments in many of the other countries of the world at the end of 1941 are not available. At the end of 1939 the gold reserves (including stabilization funds) of all countries (including the United States) totaled approximately $29,122,000,000. Adding $1,419,000,000 for new gold produced in 1940 and an estimated $1,336,000,000 for 1941 raises the total reserves of the world to approximately $31,877,000,000.

The United States Treasury silver holdings on December 31, 1941, approximated 3,280,000,000 fine ounces. This represents slightly over 100,000 tons of silver. Early in 1942 it was stated that the Treasury would lend 40,000 tons of silver for electrolytic busbars for making magnesium and for certain other war uses. The Twenty-sixth Annual Review of the Silver Market, 1941, by Handy & Harman, contains the following paragraphs regarding coinage and Indian demand.

Accretions to the gold stocks of the United States were much less in 1941 than in recent years. Nevertheless, such additions were sufficient to prevent any but nominal progress towards the goal set by the Silver Purchase Act that "one-fourth of the total monetary value of the gold and silver stocks shall be in silver." Instead of the required 25 percent, the proportion of silver at December 31, 1941, was 15.7 percent, which compares with 15.6 percent one year before.

Coinage.—According to advices from London, the Royal Mint coined and exported substantial quantities of silver during 1941, but no amounts are ascertainable. It is believed that these shipments included coinage for the Dominions and the allies of Great Britain, although the major portion consisted of Maria Theresa thalers for Ethiopia and East Africa to replace the Italian money introduced five years previously.

In Latin America, Panama authorized the coinage of additional fractional silver pieces, and the Central Bank of Ecuador was instructed to mint 5-sucre and 2-sucre coins of silver instead of issuing paper notes for the needed expansion of currency. Mexico used only a scant 300,000 ounces in 1941 to make 1-peso and 20-centavo pieces, but the silver came out of stocks purchased in 1940 and not from newly mined metal. The United States supplied native coins for Liberia, the Dominican Republic, the Dutch possessions of Curaçao and Surinam, and the Netherlands East Indies.

Although the amount of foreign coinage done in this country was considerable, the necessity to operate our mints on a 24-hour basis was caused by the tremendous demand for United States fractional currency which developed during the year, and which, according to the Director of the Mint, was attributable to defense expansion in trade, increased popularity of vending machines, and sales taxes. Between January 1 and November 30, 1941, the value of subsidiary silver in circulation (this excludes nickels and pennies) increased by $61,500,000, equivalent to 44,500,000 ounces of newly coined metal. It is also of interest that during this same period an additional 8,600,000 ounces of silver in the form of standard silver dollars was withdrawn from the banks. However, no question of silver consumption for coinage is involved in this record-breaking demand for currency by the American people, since no specific Government purchases of metal were necessitated.

497779—43——6

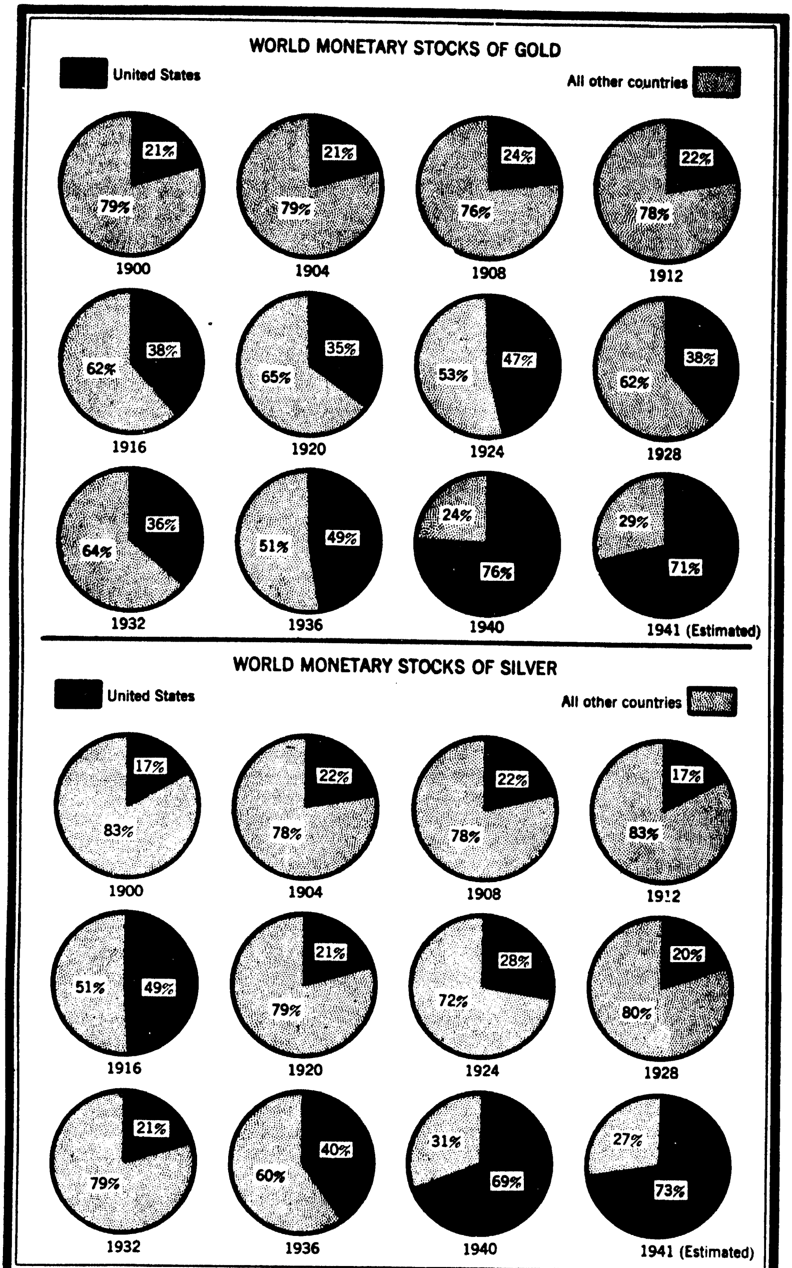

FIGURE 1.—World monetary stocks of gold and silver, 1900–1941.

Indian demand.—It has been impossible to compute statistically India's absorption of silver in 1941 because of the almost total lack of official figures or even estimates covering imports, exports, and Indian Government sales. The only pertinent information available is that in February and April 3,500,000 ounces were shipped to India from the United States and 875,000 ounces from Canada.

Also, it is believed that India acquired most of Burma's production and some 4,000,000 ounces from Australia. The sole basis for our estimate of Indian silver consumption in 1941 is an advice from Bombay which sets the figure at 40,000,000 ounces.

During the past year there has been no indication of any further hoarding of silver coin such as occurred in 1940; nor any criticism, so far as we have heard, of the debasement of the rupee. It would appear, therefore, that the steps taken by the Indian Government have satisfied the demand of the people for more currency and at the same time have provided surplus stocks of silver without the corresponding loss of foreign exchange which purchases abroad would have necessitated.

GOLD AND SILVER IN THE ARTS AND INDUSTRIES

Gold.—The average person doubtless regards gold as a special metal almost unavailable except for monetary, international trade, and exchange purposes. However, gold has a number of qualities that adapt it to many uses in industry, and it would seem that greater use might be made of the metal during the present emergency when there is a critical shortage of nearly all metals. The following comments on the uses of gold in the industries have been excerpted largely from an excellent paper by Downs.[3]

Gold has seven properties that make it particularly desirable in meeting many industrial needs: (1) Resistance to all ordinary corrosion; (2) high malleability and ductility; (3) ability to form a fast joint with ceramics; (4) ability to weld at ordinary temperatures by pressure alone; (5) very low specific heat and latent heat of fusion, making it about the easiest of the ordinary metals to heat, cool, or melt; (6) attractive color, either in the nearly pure form or as numerous alloys; (7) high conductivity for electricity.

The use of gold in jewelry is well-known. The two properties accounting mainly for the popularity of gold in articles of jewelry are attractive color and freedom from corrosion. In addition to yellow gold, white, green, blue, and purple gold can be produced. By adding varying amounts of silver, copper, zinc, nickel, or palladium, white gold is produced; adding cadmium, green gold; adding iron, blue gold; adding aluminum, purple gold.

Many articles are prepared by covering the surfaces with a layer of gold by one of the several processes described below. Gilding by the older mercurial and immersion processes has been largely replaced by electroplating. The article to be plated is made the cathode (negative pole) and a bar of gold the anode (positive pole) in a bath of potassium aurocyanide. Any thickness of plate may be obtained by controlling the operation. A thickness of 0.00005 inch is satisfactory on many articles. Gold-covered silver wire may be prepared by plating a bar of silver-copper alloy and drawing it out to wire in the usual manner. This common commodity is used for weaving into gold braid and embroideries so widely used on uniforms, vestments, and other articles. Plated gold also finds much application in instruments used in the transmission of sound, the efficiency of which depends upon the delicate electrical contact of gold-plated electrodes.

In covering surfaces with leaf gold, the extreme malleability of gold is utilized. Most leaf gold is prepared by hand-hammering the metal

[3] Downs, E., Gold and Its Scope in Industry: Chem. and Ind., vol. 61, No 14, April 4, 1942, pp. 156-160.

into sheets about four-millionths inch thick, and the leaf can be applied to nearly all kinds of surfaces. About 250 square feet of leaf can be prepared from 1 ounce of gold at a cost for the gold of about one-tenth cent per square inch. The low cost permits the leaf to be used extensively on picture frames, gilt labels of many kinds, book titles and coverings, the edges of playing cards, and numerous other articles.

The process of depositing a layer of gold by cathode sputtering or cathode dispersion has been developed rather recently. The method is applicable to articles of many different shapes, sizes, and materials. To be coated, the article is placed in a vacuum chamber provided with an aluminum anode and a gold cathode. On passing an electric current of high voltage through the chamber, gold is dispersed and deposited as a film less than one-millionth inch thick. Sputtered gold parts are used extensively in radio equipment.

The vaporization process is also used to coat objects with gold. Again, the object is placed in a vacuum chamber which also contains gold. The gold is heated electrically to its melting point, and the vapor is condensed as a molecular film on the object. Spectacle lenses processed in this way are used in the treatment of certain eye complaints.

Still another method of covering a surface with a layer of gold is through the use of rolled gold, prepared by soldering or welding gold plate of any carat onto a block of bronze, nickel silver, or silver. The block is then rolled to the desired thickness even to a covering of no more than two-millionths inch thick. Common articles made of rolled gold include spectacle frames, watch cases, pencils, jewelry, and toys. Articles with the thicker coverings have very high wearing qualities.

An interesting and important use of gold is in decorating ceramic ware. Gold applied in this way is virtually pure gold, even to the finest line. The decorating usually is done in one of two ways. In the first, the gold is prepared chemically in the amorphous form and amalgamated. Fluxes are added, and the whole is ground to a fine powder. The powder is next mixed with a suitable liquid and applied to the ware; the ware is then fired in the kiln. In the second method, a solution is prepared of complex organic gold compounds in essential oils, with materials added to give good adhesion. The solution is applied to the ware with a brush, and the ware is fired. More ware is decorated by this method than by the first. Attractive shades of ruby and rose in stained glass, jewelers' enamel, china, and porcelain ware are developed by the use of purple of Cassius (gold precipitated from a solution of gold chloride by adding stannous chloride).

The use of gold in the practice of dentistry is also well-known. Gold is a desirable dental material because it is permanent and has natural resistance to mouth secretions. It is used mainly in three ways—as fillings, dentures, and orthodentic wires. For certain types of dental work the gold is hardened by adding platinum or palladium.

Gold finds considerable use for chemical plant and laboratory ware, although the high cost of the metal limits its use considerably. Laboratory dishes and crucibles of gold-palladium alloy resist heat and chemicals, and the alloy can be substituted for platinum in many processes when the price of platinum is unduly high. Some plant equipment constructed of base metals is lined with gold to give greater resistance to the chemicals, and solid-gold stills and condensers are not unknown. Gold-platinum alloy is used to make spinnerets in the

manufacture of artificial silk, as the metal used must resist abrasion and corrosion during passage of the solution through the spinneret.

Gold also finds use in several types of special instruments, including the Pallador thermocouple—a gold-palladium-iridium-platinum couple—used for accurate temperature measurements; heat fuses, either as the pure metal or as a gold-palladium alloy, in certain electrically heated furnaces to provide protection from 960°C. to 1,500°C.; and contacts in certain electrical equipment, generally as a gold-silver-platinum alloy.

Other special commodities are made of gold because of its high resistance to corrosion. These include gold-alloy hairsprings used in highly accurate timepieces and marine chronometers; suspension strips in the most accurate galvanometers; gold plate on base-metal conductors carrying high-frequency radio currents; and gold-tipped pencils on water-meter recorders used in damp climates.

Still other interesting applications are made of gold in parabolic reflectors using infrared rays to dry paint work and as a gold alloy for brushes in motor generators employed in connection with electrical equipment that measures the speed of aircraft engines.

In therapeutics gold serves unusually well as a target in X-ray work, as container tubes for the distintegration products of radon in radium therapy, and, in the form of complex organic salts, in the treatment of certain skin diseases and rheumatoid arthritis.

Silver.—The utilization of silver in the arts and industries has shown a phenomenal increase during the past few years. Consumption has leaped from about 5,000,000 fine ounces in 1935 to some 72,000,000 fine ounces in 1941, and it is expected that consumption in 1942 will be substantially greater than in 1941. Naturally, much of this increased demand is due directly or indirectly to the war program.

Silver has many properties that make it valuable for uses in the arts and industries. For example, it is highly malleable and ductile; it ranks first among the metals in conductivity of electricity and heat; it is beautiful and has ability to take a superior finish; it is but slightly affected by common acids and is not ordinarily discolored or stained by foods and fruit juices; and it is low in cost compared with other precious, and even some base, metals.

Although nearly pure silver has many applications, it is too soft for most purposes, hence is alloyed with other metals in varying proportions. It is also used in many articles as a plating or coating on base metals or base-metal alloys. Plating is now done almost entirely by the electro method. Compounds of silver find much use in the photographic industry, as well as in medicine and chemistry.

For many years the greatest consumer of silver has been the sterling silverware industry, which in 1941 used an estimated 30,000,000 fine ounces. ("Sterling" has a fineness of 0.925, or 92.5 percent pure silver.) This amount is considerably more than double that consumed by this industry in 1940 and is attributed in great part to increased purchasing power of the public and to the greater number of marriages as a result of enlistments and inductions into the service.

The photographic industry for a number of years has ranked second in consumption of silver, followed generally by the electroplating industry, the manufacture of jewelry, optical goods and novelties, silver-clad steel tanks, evaporators, drying pans, and other equipment

for the chemical industry, and several smaller industries and uses that have consumed annually less than 1,000,000 fine ounces each.

In 1941 the war industries and others began using increasing amounts of silver; in 1942 war uses of the metal are expanding rapidly. This trend was brought about by the substitution of silver in many articles formerly made of nickel, chromium, aluminum, copper, and tin and by the industries employing silver in new ways because of the desirable properties that it possesses.

Of particular importance was the greatly increased use of silver solder and brazing alloys, which are made in a wide variety of types containing 10 to 80 percent silver, with the remainder copper, zinc, or other metals. Those in greatest use contain 40 to 50 percent silver

The silver solders and brazing alloys are of great moment in the war effort. They are used in ignition-wire shields for aircraft engines, preventing radio interference; in the manufacture of oil coolers and radiators for airplane engines; and in airplane instruments, pipe connections, parts of the fuselage, and repair work. In armament, they are employed in joining the cylinder heads in the recoil mechanisms of antiaircraft guns and field artillery pieces; in the brazing of jackets of machine guns; in the construction of torpedo tubes; and in joining the nose pieces of aerial and incendiary bomb shells and tubes. Silver brazing alloys are widely used in the construction, maintenance, and repair of ships in joining pipes, and in equipment for air conditioning and refrigeration; also, in the construction of motors, and headlight connections and pneumatic systems of automobiles; and in the assembling of parachute rip rings and the brazing of joints of army field-kitchen stoves. Numerous other uses are made of silver solder and silver brazing alloys in a wide variety of electrical equipment and appliances.

A new and important use of silver is the plating of aircraft bearings, which are coated with a thickness of 0.025 inch. This use alone probably will consume more than 5,000,000 ounces in 1942. Coin silver (90 percent pure silver) is being employed to form seals and cushion ends for pistons in the recoil chambers of antiaircraft guns and field-artillery pieces, and 9½ pounds of silver goes into the recoil mechanism of each 155-mm. gun and each 8-inch howitzer.

Silver is replacing tin in soft tin-lead solders and in high-tin Babbitt metal; nickel silver in the manufacture of watch cases; tin-antimony alloys in costume jewelry; aluminum as a reflective coating for "sealed-beam" headlights and in vacuum bottles; and brass in many important ways. It is being substituted for copper in low-voltage wiring and in busbars so extensively employed in plants manufacturing aluminum and magnesium. Silver alloyed with about 10 percent copper finds much use in electrical contacts, for which it is well-adapted because of its high conductivity of electricity and heat; too, the oxide formed at some contacts decomposes at 572° F. and returns to pure silver and thus does not build up high resistance.

Silver added in small amounts to copper improves copper to be soldered by preventing undue softening from heat; in commutator bars by insuring hardness; and in photoengravers' plates by preventing softening of the cold-rolled copper sheets processed at increased temperatures.

An alloy containing 4 percent silver has gained some commercial use as a master alloy to introduce silver into stainless steel. The

silver tends to decrease pit corrosion and to give a better surface polish.

Some progress has been made in casting silver articles weighing up to 2 ounces. Success in this field will lead to many industrial applications.

Finally, silver in various forms has considerable use in dentistry, medicine, and surgery as instruments of many types, suture wires and plates, dental fillings, cauterizing devices, and compounds used for caustic, astringent, and antiseptic purposes.

It is evident that silver occupies an important place in the war program, and the extensive research now being made on the metal undoubtedly will develop many new uses within a short time. The stockpile, once considered to be large, is disappearing at a rapid rate, and the metal is speedily taking its place with numerous other metals whose nonessential uses are being seriously curtailed or prohibited; not often has a commodity readjusted its position in commerce so abruptly.

The following table shows the net industrial consumption of gold and silver in the United States from 1901 to 1941, inclusive, in terms of dollars for gold and fine ounces for silver. The amount of each metal reclaimed and recovered from various sources is deducted from the amount issued for industrial use to give the net amount.

Net industrial consumption of gold and silver in the United States, 1901–41 [1]

Year	Gold (dollars)			Silver (fine ounces)		
	Returned from industrial use	Issued for industrial use	Net industrial consumption	Returned from industrial use	Issued for industrial use	Net industrial consumption

	35,750,798	5,129,590	30,621,208

[1] Excess of exports.

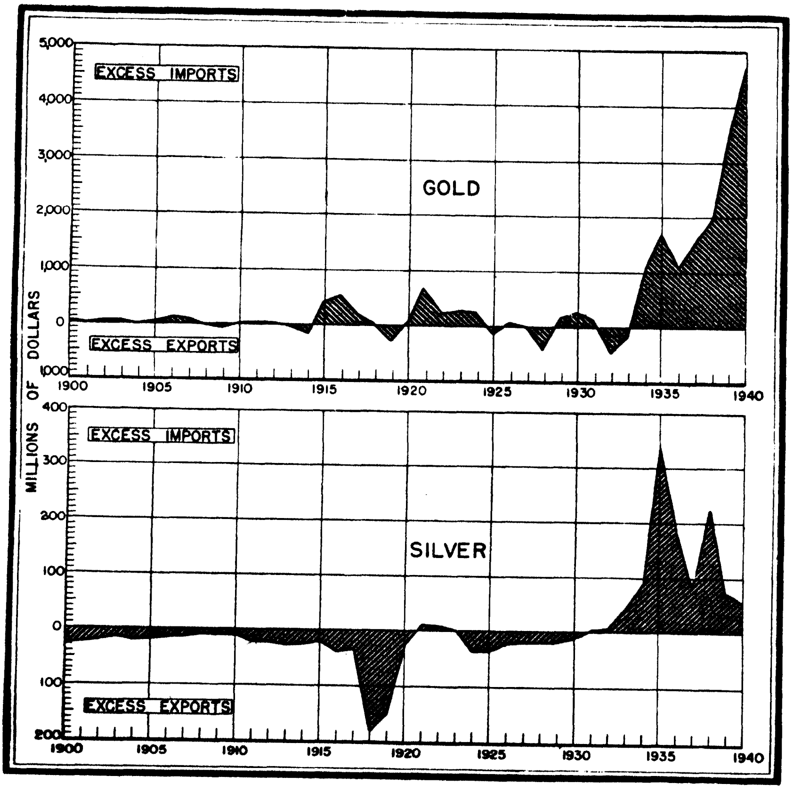

FIGURE 2.—Gold and silver imports and exports, with net movements, 1900–1940.

DOMESTIC SUPPLY

The domestic supply of new gold comes chiefly from dry and siliceous ore and from placer gravel. These two sources yielded 90 percent of the domestic gold (excluding Philippine Islands and Puerto Rico) in 1915, 80 percent in 1930, 87 percent in 1931, 93 percent in 1932, 1933, and 1934, 91 percent in 1935, 88 percent in 1936, 85 percent in 1937, 90 percent in 1938, 88 percent in 1939, 87 percent in 1940, and 86 percent in 1941. The proportionate output of gold from copper ore was 7 percent in 1915, 16 percent in 1930, 10 percent in 1931, 4 percent in 1932, 5 percent in 1933 and 1934, 7 percent in 1935, 10 percent in 1936, 12 percent in 1937, 8 percent in 1938, 10 percent in 1939, 11 percent in 1940, and 12 percent in 1941. These sources represented 96 to 98 percent of the gold supply in 1915 and 1930–41.

In 1915 dry and siliceous ore yielded in rounded figures 36 percent of the total silver; copper ore, 26 percent; lead ore, 27 percent; and zinc-lead ore, 9 percent. In 1940 dry and siliceous ores yielded 41 percent and in 1941, 41 percent; copper ore, 29 and 28 percent; lead ore, 4 and 6 percent; and zinc-lead ore (including zinc-copper and zinc-lead-copper ores), 24 and 25 percent.

MINE REPORT

METHOD OF COLLECTING STATISTICS

The first table in this report presents the official refinery figures for production of gold and silver in the United States from 1937 to 1941, as agreed upon by the Bureau of the Mint and the Bureau of Mines. These figures record the output of gold and silver bullion from domestic ore in marketable form as metals, either refined or unrefined.

To trace the gold and silver produced back to its source by States, counties, and mining districts, the Bureau of Mines systematically investigates the "mine production" of ores containing gold and silver and the output of the placer mines, the total being classified by methods of production and by kinds of ore, as well as by mining districts. The resulting figures form the basis of the mine reports.

Of the two systems for ascertaining the production of gold and silver, one is a measure of the metallurgic industry and the other of the mining industry; one reports the metal actually recovered in marketable form and the other the mine output and its recoverable content. The two methods will not produce identical results, but data for a period of years long enough to compensate for overlap or lag should agree within allowable limits of error.

Gold and silver produced in the United States, 1905–41, in fine ounces, according to mint and mine returns, in terms of recovered metals

Year	Mint		Mine	
	Gold	Silver	Gold	Silver
1905–36	109, 420, 194	1, 826, 086, 989	109, 190, 585	1, 815, 780, 860
1937	4, 804, 540	71, 941, 794	4, 834, 062	72, 128, 397
1938	5, 089, 811	62, 665, 335	5, 170, 743	62, 873, 450
1939	5, 611, 171	65, 119, 513	5, 672, 485	65, 565, 024
1940	6, 003, 105	69, 585, 734	5, 984, 163	71, 824, 746
1941	5, 976, 419	72, 336, 029	5, 881, 798	68, 483, 333
	136, 905, 240	2, 167, 735, 394	136, 733, 836	2, 156, 655, 810

Compared with the mine reports, the mint reports for the 37 years show a total excess of gold of 171,404 ounces (a difference of 0.13 percent) and a total excess of silver of 11,079,584 ounces (a difference of 0.51 percent).

UNITS OF MEASUREMENT

All tonnage figures are short tons of 2,000 pounds "dry weight"; that is, they do not include moisture. The weight unit for gold and silver is the troy ounce (480 grains). The totals are calculated upon the basis of recovered and recoverable fine gold and silver shown by assays to be contained in ore, bullion, and other material produced. Prices of gold and silver are discussed in a preceding section of this report.

MINES PRODUCING

LEADING GOLD PRODUCERS

The output of the 35 largest gold producers in the United States (Philippine Islands and Puerto Rico excluded) in 1941, none of which produced less than 19,000 ounces, was 2,528,312 fine ounces (53 percent of the total). Six of the companies, working placer mines with floating connected-bucket dredges, recovered 484,227 ounces of gold; the rest of the output of the largest producers came from lode mines. The total output of lode mines and placers producing less than 19,000 ounces each was 2,222,553 ounces.

Largest producers of gold in the United States in 1941, in order of output [1]

Rank	Operator	State	Mining district	Source of gold
1	Homestake Mining Co.	South Dakota	Whitewood	Dry and siliceous gold ore.
2	Utah Copper Co.	Utah	West Mountain	Copper ore.
3	United States Smelting, Refining & Mining Co.	Alaska	Fairbanks and Nome	Dredging gravel.
4	Golden Cycle Corporation [2]	Colorado	Cripple Creek, etc.	Dry and siliceous gold ore.
5	Phelps Dodge Corporation	Arizona	Ajo, Copper Mountain, Verde, Warren.	Copper ore.
6	Yuba Consolidated Gold Fields	California	Callahan, Oroville, Snelling, Yuba River.	Dredging gravel.
7	Alaska Juneau Gold Mining Co.	Alaska	Juneau	Dry and siliceous gold ore.
8	Idaho Maryland Mines Corporation.	California	Grass Valley-Nevada City.	Do.
9	Natomas Co.	do	Folsom	Dredging gravel.
10	Empire Star Mines Co., Ltd.	do	Browns Valley, Grass Valley-Nevada City.	Dry and siliceous ore.
11	Getchell Mine, Inc.	Nevada	Potosi	Do.
12	Howe Sound Co.	Washington	Chelan Lake	Copper ore.
13	Lava Cap Gold Mining Corporation.	California	Grass Valley-Nevada City.	Dry and siliceous ore.
14	Alaska-Pacific Consolidated Mining Co.	Alaska	Willow Creek	Dry and siliceous gold ore.
15	Nevada Consolidated Copper Corporation.	Nevada	Robinson	Copper ore.
16	Mammoth-St. Anthony, Ltd.	Arizona	Old Hat	Dry and siliceous ore.
17	United States Smelting, Refining & Mining Co. (Gold Road).	do	San Francisco	Do.
18	Snyder Mines, Inc.	Utah	Camp Floyd	Do.
19	United States Smelting, Refining & Mining Co.	do	West Mountain and Tintic.	Zinc-lead ore, lead ore, dry and siliceous gold-silver ore.
20	Consolidated Coppermines Corporation.	Nevada	Robinson	Copper ore.

[1] Philippine Islands excluded.
[2] Custom mill. Includes mainly ore from Cresson, Portland, Ajax, Vindicator, and other mines in Cripple Creek district, Colorado, but also from other districts in Colorado.

Largest producers of gold in the United States in 1941, in order of output—Contd.

Rank	Operator	State	Mining district	Source of gold
21	Bald Mountain Mining Co.	South Dakota	Trojan	Dry and siliceous gold ore.
22	Gold Hill Dredging Co	California	Camanche, Oroville	Dredging gravel.
23	Central Eureka Mining Co	do	Mother Lode	Dry and siliceous ore.
24	Capital Dredging Co	do	Folsom	Dredging gravel.
25	New Jersey Zinc Co., Empire Zinc Division.	Colorado	Battle Mountain	Copper ore.
26	Knob Hill Mines, Inc	Washington	Republic	Dry and siliceous gold ore.
27	Talache Mines, Inc	Idaho	Middle Boise	Do.
28	Argonaut Mining Co., Ltd	California	Mother Lode	Dry and siliceous ore.
29	Golden Queen Mining Co	do	Mojave	Do.
30	Carson Hill Gold Mining Corporation.	do	Mother Lode	Do.
31	Telluride Mines, Inc. ormerly Veta Mines, Inc.).	Colorado	Upper San Miguel	Dry and siliceous gold-silver ore.
32	Anaconda Copper Mining Co.	Montana	Summit Valley or Butte.	Copper ore, zinc-lead ore, dry and siliceous gold-silver ore.
33	Manhattan Gold Dredging Co.	Nevada	Manhattan	Dredging gravel.
34	Anaconda Copper Mining Co. (West Mayflower mine).	Montana	Renova	Dry and siliceous gold ore.
35	Prescott Lease (E. L. Cord)	Nevada	Silver Peak	Dry and siliceous ore

LEADING SILVER PRODUCERS

The output of silver from the 50 leading silver-producing companies in 1941, none of which produced less than 199,000 ounces, was 53,638,081 ounces—80 percent of the total mine output of the United States (Philippine Islands and Puerto Rico excluded); the remaining 13,426,788 ounces (placer production excluded) came from about 5,000 lode mines, many of which derive a substantial net income from the silver content.

Largest producers of silver in the United States in 1941, in order of output

Rank	Operator	State	Mining district	Source of silver
1	Anaconda Copper Mining Co.	Montana	Summit Valley or Butte.	Copper ore, zinc-lead ore, dry and siliceous gold-silver ore.
2	Sunshine Mining Co	Idaho	Evolution	Dry and siliceous silver ore.
3	New Jersey Zinc Co., Empire Zinc Division.	Colorado	Battle Mountain	Copper ore.
4	Phelps Dodge Corporation	Arizona	Ajo, Copper Mountain, Verde, Warren.	Do.
5	United States Smelting, Refining & Mining Co.	Utah	West Mountain and Tintic.	Zinc-lead ore, lead ore, dry and siliceous gold-silver ore.
6	Utah Copper Co	do	West Mountain	Copper ore.
7	Bunker Hill & Sullivan Mining & Concentrating Co	Idaho	Yreka	Zinc-lead ore, dry and siliceous silver ore.
8	Tintic Standard Mining Co.	Utah	Tintic	Dry and siliceous silver ore, lead ore.
9	Coeur d'Alene Mines Corporation.	Idaho	Evolution	Dry and siliceous silver ore.
10	Federal Mining & Smelting Co.	do	Hunter and Yreka	Zinc-lead ore, lead ore.
11	Silver King Coalition Mines Co.	Utah	Uintah	Zinc-lead ore.
12	American Metal Co. (Presidio mine).	Texas	Shafter	Dry and siliceous silver ore.
13	Polaris Mining Co	Idaho	Evolution	Do.
14	Hecla Mining Co	do	Lelande	Zinc-lead ore, lead ore.
15	Triumph Mining Co	do	Warm Springs	Zinc-lead ore

Largest producers of silver in the United States in 1941, in order of output—Con.

Rank	Operator	State	Mining district	Source of silver
16	Desert Silver, Inc	Nevada	Silver Peak	Dry and siliceous ore.
17	Emperius Mining Co	Colorado	Creede	Dry and siliceous silver ore.
18	Park City Consolidated Mines Co	Utah	Blue Ledge	Zinc-lead ore.
19	Anaconda Copper Mining Co. (Flathead mine)	Montana	Hog Heaven	Dry and siliceous silver ore, lead ore.
20	Lexington Mining Co	do	Montana (Neihart)	Do.
21	Magma Copper Co	Arizona	Pioneer	Copper ore, zinc-copper ore.
22	New Park Mining Co	Utah	Park City	Zinc-lead ore.
23	Combined Metals Reduction Co	Nevada	Pioche	Do.
24	Chief Consolidated Mining Co	Utah	Tintic	Dry and siliceous gold-silver ore, zinc-lead ore, lead ore.
25	Blackhawk Consolidated Mines Co	New Mexico	Mogollon	Dry and siliceous gold-silver ore
26	West Coast Mines, Inc	Nevada	Barrett Springs	Dry and siliceous ore
27	Park Utah Consolidated Mines Co.	Utah	Park City	Zinc-lead ore, lead ore
28	Shattuck Denn Mining Corporation	Arizona	Warren	Copper ore, zinc-lead ore.
29	Cactus Mines Co	California	Mojave	Dry and siliceous ore
30	St Joseph Lead Co	Missouri	Southeastern Missouri	Lead ore.
31	Ground Hog Unit, American Smelting & Refining Co.	New Mexico	Central	Zinc-lead ore, lead ore, copper ore
32	Anaconda Copper Mining Co (Emma and Ophir)	Montana	Summit Valley or Butte	Zinc-lead ore, manganese-zinc-lead ore.
33	Lava Cap Gold Mining Corporation	California	Grass Valley-Nevada City.	Dry and siliceous ore.
34	Telluride Mines, Inc (formerly Veta Mines, Inc).	Colorado	Upper San Miguel	Dry and siliceous gold-silver ore.
35	American Smelting & Refining Co. (Trench Unit)	Utah	Harshaw	Zinc-lead ore.
36	Philipsburg Mining Co	Montana	Flint Creek	Dry and siliceous gold-silver ore
37	Combined Metals Reduction Co. (Park-Bingham group)	Utah	West Mountain	Zinc-lead ore, dry and siliceous gold ore, dry and siliceous gold-silver ore
38	Lessees of the Tonopah Mining Co. of Nevada	Nevada	Tonopah	Dry and siliceous ore
39	Shenandoah-Dives Mining Co.	Colorado	Animas	Zinc-lead ore.
40	Bristol Silver Mines Co	Nevada	Jack Rabbit	Lead ore.
41	Iron King Mining Co	Arizona	Big Bug	Zinc-lead ore, dry and siliceous gold-silver ore.
42	Summit King Mines, Ltd	Nevada	Sand Springs	Dry and siliceous ore.
43	Sherman Lead Co	Idaho	Lelande	Lead ore
44	Combined Metals Reduction Co (West Calumet mine).	Utah	Rush Valley	Zinc-lead ore, lead ore, dry and siliceous gold-silver ore
45	DeLamar Mining & Milling Co.	Idaho	Carson	Dry and siliceous gold-silver ore
46	Florence Mining Co	Montana	Montana (Neihart)	Dry and siliceous silver ore.
47	Golden Queen Mining Co	California	Mojave	Dry and siliceous ore

NUMBER OF MINES

The following table indicates the number of mines that produced gold and silver in 1940 and 1941. The placers are those in which gold and silver in natural alloy and, in a few placers, platinum are recovered from gravel and sand, whether by hand washing, sluicing, hydraulicking, drifting (in frozen ground or ancient buried river channels), or dredging. The lode mines are those yielding gold and silver from ore as distinguished from gravel, mainly from under-

ground workings, and include those that yield ore mined chiefly for copper, lead, or zinc but that contribute the precious metals as byproducts. In addition to the producing mines enumerated here many properties were being prospected and developed, and many other mining claims were being held by assessment work only.

The enumeration of placer mines is less satisfactory than that of lode mines, because some are operated only temporarily and are individually small. As far as possible the unit, as for lode mines, is not the operator but the mining claim or group of claims.

Number of mines in the United States producing gold and silver, 1940–41, by States

MINE PRODUCTION

SUMMARY

The following table gives the mine production of gold and silver in 1940 and 1941, by States, in terms of recovered metals, as calculated by the Bureau of Mines from reports from the producing mines. The annual percentage gains in gold production in the years following the 69-percent increase in the price of gold are as follows: 1934 over 1933, 19 percent; 1935 over 1934, 18 percent; 1936 over 1935, 19 percent; 1937 over 1936, 9 percent; 1938 over 1937, 7 percent; 1939 over 1938, 10 percent; 1940 over 1939, 5 percent; but 1941 decreased from 1940, 2 percent. The total gain in 1940 over 1933 was 128 percent. The output of silver decreased 5 percent in 1941 from 1940 but was 194 percent above that in 1933.

ORE PRODUCTION, CLASSIFICATION, METAL YIELD, AND METHODS OF RECOVERY

The best index of lode mining is the quantity and metallic content of ore mined rather than the number of mines or operators. The following tables give details of classes of ore, metal yield in fine ounces of gold and silver to the ton, and gold and silver output by classes of ore and by methods of recovery, embracing all ores that produced gold and silver in the United States (excluding the Philippine Islands and Puerto Rico) in 1941. The individual State chapters from which these tables were compiled contain additional tables and text on the subject and may be found elsewhere in this volume.

The classification originally adopted in 1905 on the basis of smelter terminology, smelter settlement contracts, and smelter recovery has been used continuously in succeeding years, except for modifications necessitated by the improvement in recovery of metals and the lowering of grade of complex ores treated, accomplished by improved mill concentration processes. A "dry" ore is one that carries so little lead or copper that by itself in quantity it would not satisfy the requirements for the smelter charge in lead smelting or copper smelting, respectively. The copper ores include those smelting ores that contain 2.5 percent dry assay or more of copper (or less than this percentage if no other metal is present), or those ores concentrated chiefly for their copper content. The lead ores are those that contain 5 percent dry assay (minimum lead smelting charge requires 7.5 to 8.5 percent wet assay) or more of lead, irrespective of precious-metal content; an ore that carries any grade of lead exclusively is called a lead ore. Zinc smelting ores (chiefly oxides) range from 16 to 45 percent zinc; zinc concentrating ores include any grade of zinc ore that makes marketable zinc concentrate, irrespective of precious-metal content. The mixed ores are combinations of those enumerated. The smelter classification applies to concentrates.

Siliceous (silica [4] in excess of iron) gold, gold-silver, and silver ores containing too little copper, lead, or zinc to be classified as copper, lead, zinc, or mixed ores are called "dry" ores regardless of the ratio of concentration, except low-grade ore milled chiefly for its copper content and having very little or no precious-metal content (chiefly the "porphyry coppers") and ores from which separate products of lead concentrates and zinc concentrates are made. The crude ore into the mill in these two exceptional instances thus takes its name from its products—a name that is also justified by the mineralogical content and final recovery of metals. The "dry and siliceous ores" thus, by elimination, include both dry siliceous and irony, but chiefly siliceous, ores valuable for their gold and silver content, regardless of method of treatment, and dry fluxing ores carrying considerable quantities of iron and manganese oxides, or iron sulfide, and very small quantities of gold and silver. Dry and siliceous gold ores are those that by inspection are overwhelmingly of gold content; a similar qualification applies to silver ores; decision as to "gold-silver" ore is made arbitrarily on a basis of value, using the rule that the metal of lower value is not used in the bimetal classification unless its value is equal to or over one-quarter of the combined value of gold and silver.

The lead, zinc, and zinc-lead ores in most districts in the Eastern and Central States carry no appreciable quantity of gold or silver; such ores are excluded from this report unless otherwise indicated.

[3] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.
[4] The quantity from which this average is derived is 2,746 ounces, which includes 2,422 ounces from magnetite-pyrite-chalcopyrite ore from Pennsylvania.
[5] The quantity from which this average is derived is 59,221 ounces, which includes 15,016 ounces from magnetite-pyrite-chalcopyrite ore from Pennsylvania
[6] Includes zinc-copper ore from Arizona and zinc-lead-copper ore from Utah.
[7] Includes 170,592 tons of current slag fumed.
[8] Includes 29,658 tons zinc-lead slag.
[9] Less than 0.0005 ounce per ton.

Mine production of gold in the United States in 1941, by States and sources, in fine ounces, in terms of recovered metals [1]

[1] Philippine Islands and Puerto Rico excluded. [2] Less than 0.005 percent.

PLACERS

Dredging.—Placer gold is obtained largely from gravels handled by connected-bucket floating dredges, which recovered approximately 58 percent of the total output from placers in the United States (Philippine Islands and Puerto Rico excluded) in 1941 and 60 percent in 1940. The quantity of gold recovered by dredges from the inception of the industry as a commercial factor in 1896 to the end of 1941 is recorded as 18,385,002 ounces, originating by States as follows: California, 11,255,979 ounces; Alaska, 4,908,196 (including the production from two Becker-Hopkins single-dipper dredges and some gold by hydraulicking); Montana, 659,800; Idaho, 575,660; Colorado, 440,672; Oregon, 445,405; and other States, 99.290. The out-

put in 1941 was 867,005 ounces from 123 dredges, of which California produced 418,282 ounces from 47 dredges; Alaska, 307,087 from 47 dredges; Idaho, 52,358 from 12 dredges; Montana, 33,844 from 7 dredges; Oregon, 24,131 from 7 dredges; and Colorado, 10,622 from 2 dredges.

Connected-bucket floating gold dredges operated in the United States, 1940–41, by companies and districts

Gold produced in the United States by connected-bucket floating dredges, 1937–41, in fine ounces

Year	Dredges	California	Alaska	Other States [1]	Total
1937	105	322,961	255,568	65,614	644,143
1938	115	375,296	278,442	82,686	736,424
1939	114	370,264	304,995	112,472	787,731
1940	122	414,966	354,806	134,377	904,149
1941	123	418,282	307,087	141,636	867,005

[1] Colorado, Idaho, Montana, Nevada, and Oregon.

Other placer-mining methods.—From 1932 through 1941 dragline and power-shovel excavators operated in connection with dry-land and floating amalgamating and sluicing plants have been widely used in placer mining. In 1941 approximately 30 percent of the total output of placer gold, including that of Alaska and excluding that of the Philippine Islands, was recovered at such plants, and 12 percent was produced by old-established mining methods, such as hydraulicking, drift mining, sluicing, and rocking.

Additional information on placer-mining methods may be found in the State reviews in the Minerals Yearbook and Mineral Resources series.

WORLD ASPECTS

WORLD PRODUCTION

According to the Bureau of the Mint, the world output of gold and silver from 1493 to 1940 is 1,375,164,679 fine ounces of gold valued at $31,910,089,774 and 17,244,356,061 fine ounces of silver valued at $15,451,255,865 (see figs. 3 and 4).

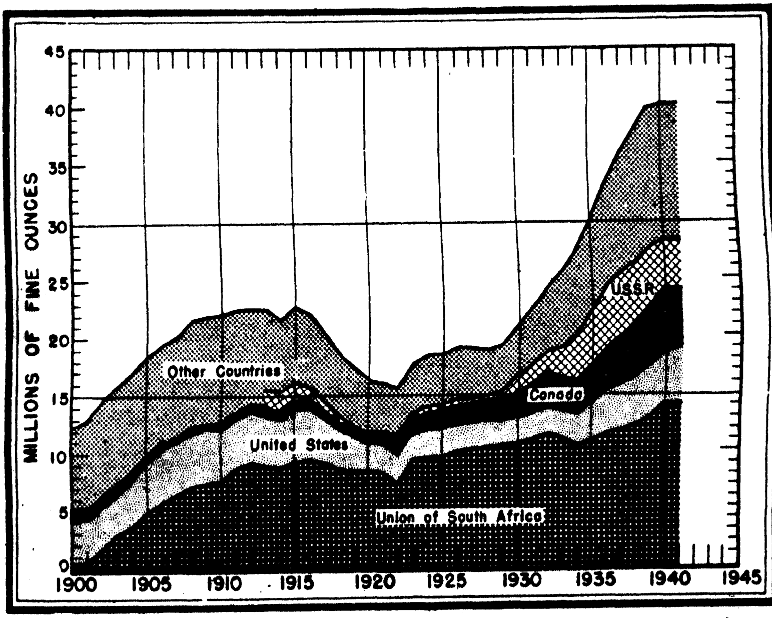

FIGURE 3.—World production of gold, 1900–1941. (Figures for 1941 are preliminary.)

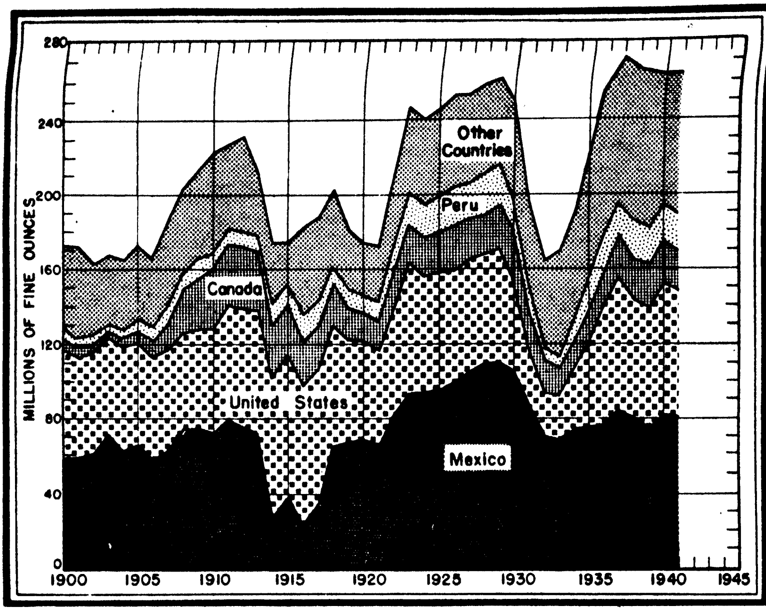

FIGURE 4.—World production of silver, 1900–1941. (Figures for 1941 are preliminary.)

The following tables show the world output of gold and silver from 1937 to 1941.

World production of gold, 1937–41, by countries, in fine ounces [1]

Country	1937	1938	1939	1940	1941
North America:

[1] Preliminary world gold production table prepared with revisions and adjustments by B. B. Waldbauer, Foreign Minerals Division, and Frederick Betz, Metal Economics Division, Bureau of Mines, in cooperation with the Office of the Director of the Mint. Figures used were derived in part from the Statistical Yearbook of the League of Nations and from the American Bureau of Metal Statistics. No official statistics are issued by Government of U. S. S. R., consequently figures released by the various authorities vary widely and are irreconcilable. In some countries accurate figures are not possible to obtain, due to clandestine trade in gold.

[2] Refinery production.

[3] Approximate production.

[4] Exports.

[5] Imports into United States.

[6] Data not available. Estimate included in total.

[7] Purchases by the State Central Bank.

[8] Conjectural figure published by the American Bureau of Metal Statistics (New York), Annual Issue.

[9] Beginning with 1939, Burmese production included with British India.

REVIEW BY COUNTRIES

Because of lack of communications between the United States and the countries dominated by the Axis Powers and the censorship imposed by some of the other countries, it has been impossible to obtain information on gold and silver mining in these countries. Few data have come even from some of the countries in the Western Hemisphere. The following summary covers the Philippines and those

countries of the Western Hemisphere from which information has been obtained.

PHILIPPINE ISLANDS

Gold production in the Philippine Islands during 1941 according to mint returns continued to gain as it has each year since 1927, reaching an all-time high of 1,144,332 fine ounces valued at $40,051,600. This represents an increase of 4,206 fine ounces, or 0.4 percent, over 1940, the previous record year. The total value of gold output from 1907 to 1941, inclusive, is computed at $270,540,406.

Silver production, on the other hand, declined in 1941 from 1940, decreasing 39,102 fine ounces, or 3 percent.

The following historical review and description of the gold mines and districts in the Philippine Islands has been prepared by Charles White Merrill.[6]

Since 1936, when Philippine Islands gold production passed that of South Dakota and Alaska, California has been the only political subdivision under the United States flag with a larger output. With the opening of hostilities between the United States and Japan December 7, 1941, however, the Islands' gold-mining industry was suspended almost immediately.

Gold mining in the Philippine Islands antedates written history. Much evidence of widespread mining activities during the Spanish colonial period remains, but production never reached great size. With occupation and pacification of the Islands by the United States, American prospecting techniques were applied, and many promising districts were discovered or rediscovered. Nevertheless, for over 30 years development of gold-mining enterprises was very slow. Even as late as 1931 the value of mine output was only $3,762,433, or less than 10 percent of the value of output in 1940 (1,114,201 fine ounces valued at $38,997,035).

The rapid rise of the industry after 1931 may have been accelerated by the belief that Philippine independence or Japanese conquest would make exploitation less profitable or impossible. Conditions at leading producing properties just before the Japanese invasion, however, gave ample evidence that the very rapid expansion had not created an unhealthy condition in the industry.

Principal mines.—Figure 5 shows the location of the principal mining districts in the Islands. The Baguio district in northern Luzon is the oldest and by far the most important. Also on Luzon is the Paracale district. The most productive mineral area on Mindanao Island is the Surigao district, and on Masbate Island the Masbate district is the leading mining area; the map locates the principal companies operating in the several districts. Three groups of companies, generally referred to by the names of the men holding controlling interests—the Haussermann group, Soriano group, and Marsman group—produced nine-tenths of the Philippine gold in 1940. The following paragraphs summarize the last complete details on the producing companies.

Modern mining in the Philippine Islands can be said to date from June 24, 1903, when the Benguet Consolidated Mining Co. was incorporated; in 1914 John W. Haussermann was placed in charge, and

[6] Many data have been excerpted from the Philippine Mining Yearbook for 1940: Chamber of Mines of the Philippines, 1941.

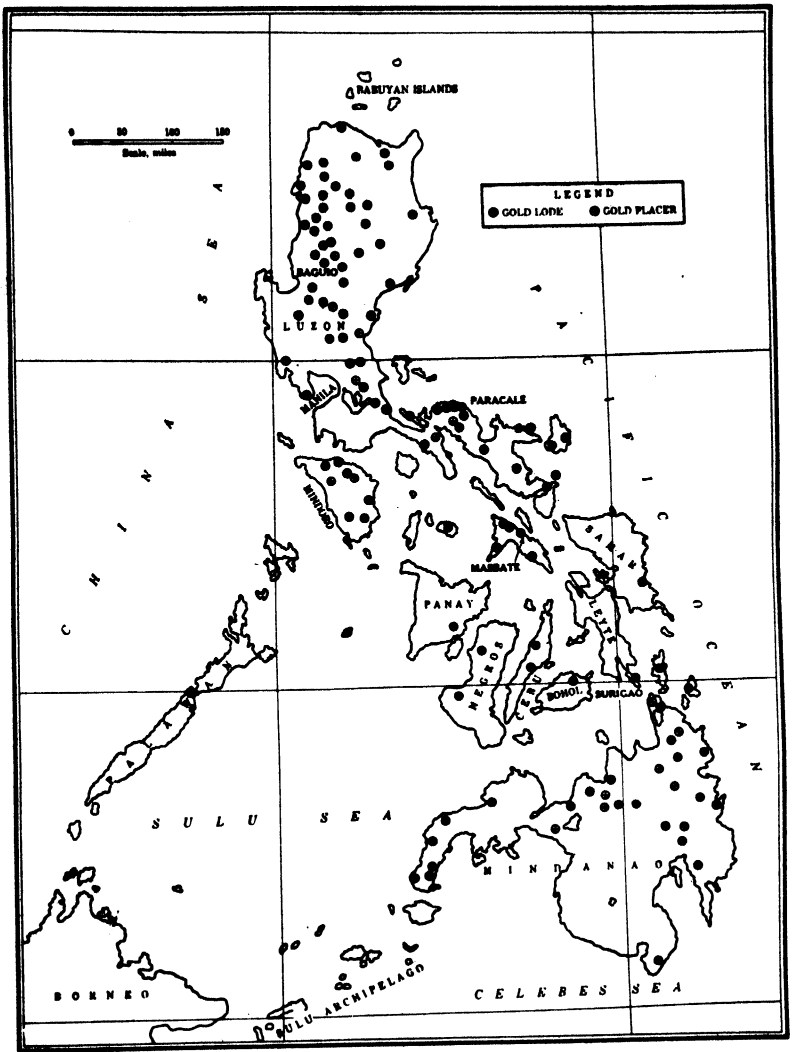

FIGURE 5.—Principal mining districts in the Philippine Islands.

in 1915 the first of a long series of dividends was paid. In 1940 the company produced 154,922 fine ounces of gold and 102,738 fine ounces of silver from 467,130 tons of ore mined in the Baguio district; the ore was treated in the company 1,250-ton cyanide plant. Positive ore reserves January 1, 1941, assured 1 year's operation, and probable ore, 2 additional years. Dividends for 1940 were $3,900,000.

The Balatoc Mining Co.,[6] another member of the Haussermann group of companies, is also situated in the Baguio district. In 1940, when 187,282 ounces of gold and 165,321 ounces of silver were recovered from 738,716 tons of ore, it was the leading gold producer of the Islands; the ore was treated in a 2,000-ton flotation-cyanidation

[6] *See also* Hezzelwood, George W., Development of Mining Methods at Balatoc Mine: Min. Technol., Am. Inst. Min. and Met. Eng., vol. 6, No. 1, January 1942, pp. 1-27.

plant. Positive ore reserves January 1, 1941, assured 2 years' operation and probable ore an additional 1½ years. Dividends in 1940 totaled $2,100,000.

The Cal Horr Mine, a Haussermann company, operated the Cal Horr and Ukab mines in the Baguio district. In 1940, the two properties produced 85,162 tons of ore from which 20,356 ounces of gold and 13,600 ounces of silver were recovered in the company 250-ton cyanide mill. Proved ore reserves were small.

The Ipo Gold Mines, Inc., was the only company in the Haussermann group to prove unprofitable in 1940; limited ore reserves indicated a short life for the enterprise. In 1940, 71,145 tons of ore treated in the company 200-ton all-slime cyanide mill yielded 9,907 ounces of gold and 8,419 ounces of silver.

The Marsman group of mining companies included Coco Grove, Inc., Itogon Mining Co., Philippine Smelting Co., San Mauricio Mining Co., Suyoc Consolidated Mining Co., and United Paracale Mining Co. Coco Grove, Inc.,[7] Paracale district, operated two connected-bucket dredges, each with a capacity of 165,000 cubic yards a month, and in 1940 washed 3,897,357 cubic yards of gravel which yielded 23,045 ounces of gold and 3,517 ounces of silver; these figures represent 85 percent of the gravel washed and 82 percent of the placer gold recovered in the Philippine Islands. On January 1, 1941, reserves were 14,320,000 cubic yards of gravel valued at $3,007,200. Production by Coco Grove, Inc., in 1938 revived the Paracale district placers, which already had a record of $9,000,000 of placer gold from dredging carried on between 1915 and 1922.

The Itogon Mining Co. worked its mine in the Baguio district and treated 327,062 tons of ore in a 1,000-ton all-slime cyanide mill in 1940; 75,996 ounces of gold and 33,401 ounces of silver were recovered. Ore reserves January 1, 1941, were 563,100 tons with a gross value of $4,817,820. In 1940, $500,000 was paid in dividends.

The San Mauricio Mining Co. worked a mine in the Paracale district discovered in 1629 by Diego de Espina; refractory ore was treated in the company 550-ton amalgamation-flotation mill. In 1940, the treatment of 182,716 tons of ore yielded 80,790 ounces of gold and 122,317 ounces of silver; the concentrates contained substantial quantities of lead and copper. Reserves January 1, 1941, assured ore for 2½ years' operation. Dividends paid in 1940 totaled $700,000.

The Suyoc Consolidated Mining Co. operated in the Suyoc district in northern Luzon Island. During 1940, 79,152 tons of ore were treated in the company 350-ton flotation-cyanidation mill and yielded 28,654 ounces of gold and 13,610 ounces of silver. The ore reserves January 1, 1941, were adequate for 3 years' operation at the 1940 rate. Dividends paid in 1940 totaled $98,750.

The United Paracale Mining Co. operated four mines in the Paracale district; 47,293 ounces of gold and 116,255 ounces of silver were recovered from 126,321 tons of ore treated in a 370-ton mill. Ore reserves January 1, 1941, were sufficient to maintain the 1940 production rate for 2 years. Dividends paid in 1940 totaled $130,000.

The Soriano group of properties included the Antamok Goldfields Mining Co., Batong Buhay Gold Mines, Inc., I. X. L. Mining Co., Masbate Consolidated Mining Co., North Camarines Gold Mining

[7] *See also* Johnson, G. R., Coco Grove Dredges Have Interesting Features: Eng. and Min. Jour., vol. 143, No. 4, April 1942, pp. 59–61.

Co., Paracale Gold Mining Co., and Paracale National Gold Mining Co. The Antamok Goldfields Mining Co. (Baguio district) treated 193,966 tons of ore in an 800-ton cyanide plant and recovered 37,112 ounces of gold and 16,136 ounces of silver in 1940. Dividends paid in 1940 totaled $137,500; ore reserves were small.

The I. X. L. Mining Co. worked a group of claims in the Masbate district; 144,868 tons of ore treated in the company 400-ton mill yielded 38,618 ounces of gold and 267,170 ounces of silver. The company was the largest silver producer in the Islands. Ore reserves January 1, 1941, were sufficient for almost 2 years' operation at the 1940 rate. Dividends paid in 1940 totaled $600,000.

The Masbate Consolidated Mining Co., Masbate district, increased the capacity of its 3,000-ton cyanide mill to 3,800 tons in 1941 by adding a colloidal-slime-treatment plant. Before the increase in capacity the mill, which treated 1,078,573 tons of ore (24 percent of the gold ore milled in 1940) and recovered 90,080 ounces of gold and 62,551 ounces of silver, already had the largest capacity in the Philippines. Despite the rapid rate of mining, the reserves January 1, 1941, were sufficient for over 6 years' production at the 1940 rate. Dividends paid in 1940 totaled $500,000. The Masbate Consolidated Mining Co. includes in its holdings the property from which the Colorado Mining Co. is credited with recovering $6,000,000 of gold from 600,000 tons of ore between 1911 and 1925 and the property from which the Syndicate Mining Co. is credited with recovering $6,500,000 from 800,000 tons of ore between 1914 and 1935. The gold-mining operation under the present management is the oldest continuous one in the Philippine Islands.

The North Camarines Gold Mining Co. operated in the Paracale district in 1940; 63,944 tons of ore treated in the company 400-ton amalgamation-cyanidation-flotation mill yielded 19,967 ounces of gold and 24,343 ounces of silver. Ore reserves were small; no dividends were paid in 1940. The outputs of the Batong Buhay Gold Mines, Inc., the Paracale National Gold Mining Co., and the Paracale Gold Mining Co. were much smaller than those of the other Soriano companies.

The larger gold producers not associated with one of the three leading management companies were: Baguio Gold Mining Co., Big Wedge Mining Co., Baguio district; Capsay Mining Co., Masbate district; Mindanao Mother Lode Mines, Inc., and Surigao Consolidated Mining Co., Inc., Surigao district; and Treasure Island Mining Co. on Lahuy Island.

During 1940, the Baguio Gold Mining Co. recovered 31,325 ounces of gold and 21,576 ounces of silver from 142,545 tons of ore treated in the company 400-ton all-slime cyanide plant. Ore reserves January 1, 1941, were equal to 1½ years' production at the 1940 rate. Dividends paid in 1940 totaled $194,985. The Big Wedge Mining Co. recovered 27,726 ounces of gold and 25,057 ounces of silver from 75,642 tons of ore treated in the company 225-ton cyanidation-flotation mill. Dividends paid in 1940 totaled $155,538. Ore reserves were adequate to assure 4 years' operation at the 1940 rate. The Capsay Mining Co. recovered 14,888 ounces of gold and 11,585 ounces of silver from 43,183 tons of gold ore treated in the company 150-ton amalgamation-cyanidation plant. On January 1, 1941, enough ore was blocked out to assure operation at the 1940 rate for 1 year. No dividends were paid in 1940. The Mindanao Mother Lode Mines,

Inc., recovered 31,063 ounces of gold and 43,683 ounces of silver from 68,487 tons of ore treated in the company 200-ton flotation-cyanidation mill during 1940 and paid dividends totaling $200,000. Ore reserves January 1, 1941, sufficed to assure 1½ years' operation at the 1940 rate. Very favorable developments at this property during 1941 resulted in the monthly production rate approaching 12,000 ounces of gold late in 1941. The Surigao Consolidated Mining Co. recovered 30,898 ounces of gold and 40,470 ounces of silver from 117,012 tons of ore treated in the company 325-ton flotation-cyanidation mill. Dividends paid in 1940 totaled $204,680. Ore reserves January 1, 1941, were equal to 4 years' production at the 1940 rate. The Treasure Island Mining Co. treated 57,843 tons of ore in a 200-ton cyanidation mill and recovered 21,918 ounces of gold and 4,759 ounces of silver. No dividends were paid in 1940. The ore reserves January 1, 1941, approximated 1 year's production at the 1940 rate.

Japanese invasion.—The position of the Philippine Islands exposed them to almost immediate attack by Japan; enemy reconnaissance planes were over the Islands almost simultaneously with the bombing of Pearl Harbor, December 7, 1941 (about 4 a. m., December 8, in the Philippines). First landings of Japanese troops were reported at Aparri, Luzon Island, December 10. By December 13, enemy landing parties were established at Aparri, Vigan, Lingayen, and Legaspi, all on the Island of Luzon. The Japanese had landed in force at Davao on Mindanao Island by December 20; 80 transports were sighted December 22 off Lingayen Gulf, northwest Luzon, and the major invasion drive began. On December 26, American forces began their withdrawal from Manila, where virtually all mining companies in the Philippine Islands maintained their main offices, and military authorities declared it an "open" city. By January 4, 1942, organized American and Filipino resistance was confined to Bataan Peninsula and the Corregidor group of fortresses. Bataan fell April 9, and Corregidor capitulated May 6. The Japanese continued their subjugation of isolated guerilla bands.

Although reports from managements of gold mines in the Philippine Islands have been fragmentary, all companies appear to have prepared for complete suspension of operations as soon as war was declared. Underground machinery, including pumps, was removed for storage at the surface. Some expendable supplies, such as fuel oil and explosives, seem to have been requisitioned by the military authorities, and other such supplies were destroyed. Structures, equipment, and machinery at the properties apparently were left undamaged, except for Diesel-power units, which, at least at most properties, were reported destroyed. As Diesel engines have been the gold industry's sole source of power (except for a very small hydroelectric installation at the Benguet Consolidated Mining Co. property), the Japanese will find it impossible to resume production without providing a source of power. It is thought no attempts were made to delay entry into the mines by blasting entries, but removal of the pumps assured that most productive workings would rapidly fill with water. As the mines are situated in nonagricultural areas, it is presumed that the workers dispersed to the lowlands almost immediately. One company is reported to have provided each employee with a dismissal bonus equal to 3 months' wages. As large-scale mining was a very new industry in the Philippine Islands, most of the workers had experience in other occupations, prin-

cipally farming, and it is believed that most gold-mine employees returned to them. The mining staffs, made up largely of Americans, were ordered to Manila, where it was hoped that the open-city declaration of the military authorities would insure their safety.

The invasion progressed so rapidly that little time was given the company managements to consider courses of action; the eventual complete defeat of the Japanese seems to have been assumed. During the occupation, however, a number of possibilities presented themselves, which included reopening of the mines by the Japanese, stripping the properties of machinery either for use elsewhere or as a source of scrap metal, or complete quiescence at the properties.

Some of company officials have stated that the first possibility would be the least injurious to the interests of the mine owners; reserves, being in narrow veins at most of the mines, could not be extracted very rapidly, and operation would tend to preserve the plants and organizations during hostilities. The Japanese need for gold, particularly to foster treason on the Asiatic mainland, has been suggested as an outstanding reason for reopening the gold mines. It seemed not impossible that some method would be found to exact reparations for the benefit of the owners. Possibility that plants would be looted for machinery and scrap was evident, because much of the equipment could be very helpful to the invaders for use elsewhere and because of chronic shortage of metallic scrap in Japan. When the Japanese established complete control of Manila Bay, it became practicable for them to export even the largest units of machinery from the deep-water docks of Manila; whereas, while the American forces at Corregidor commanded the entrance to the bay, there were no Luzon harbors in the hands of the Japanese from which cargoes could be transferred to ocean-going vessels except with lighters. Nothing short of overwhelming military force could have brought the expanding Philippine mining industry to such a sudden halt; the healthy condition of the gold industry at the time of the invasion, however, gives promise of prompt revival when peace is restored.

DOMINION OF CANADA AND NEWFOUNDLAND

Canada.—Gold production in Canada reached a record total of 5,351,689 fine ounces valued at $206,040,026 in 1941 compared with 5,311,145 fine ounces valued at $204,479,083 in 1940. Canada contributes about 12 percent of the total world production of gold and is exceeded only by South Africa and Russia as a world producer.

Canadian production of gold in 1941 was distributed among the various provinces as follows:

	Fine ounces		*Fine ounces*
Ontario	3, 190, 786	Northwest Territories	77, 334
Quebec	1, 088, 860	Yukon	70, 959
British Columbia	615, 838	Nova Scotia	19, 170
Manitoba	150, 523	Alberta	215
Saskatchewan	138, 004		

In Ontario virtually all the gold comes from quartz veins; a small amount is obtained as a byproduct in the refining of nickel and copper. The principal producing areas are Porcupine and Kirkland Lake. The 72 mills with an operating capacity of 36,800 tons a day were in continuous operation in 1941.

In Quebec, also, most of the gold comes from quartz veins, although the largest single producer is the Noranda gold-copper mine. In 1941

497779—43——8

the Province had 24 mills in continuous operation, with a daily capacity of 13,850 tons.

In British Columbia the chief source of gold is gold-quartz mines. Next in importance are the gold-bearing base-metal ores; a relatively small amount is obtained from placer operations. During 1941, 30 mills with a total daily capacity of 5,300 tons were in operation.

Manitoba produces about 55 percent of its total gold from gold-quartz ores and 45 percent from copper-zinc-gold ores. There were five mills operating in 1941; the total capacity was 5,025 tons a day.

In Saskatchewan the production is mainly from that portion of the Flin Flon copper-zinc-gold mine lying within the Province. One mill with a capacity of 1,500 tons a day was in operation in 1941.

Production of gold was begun in the Northwest Territories in 1938 and is obtained from the Yellowknife River and adjoining areas north of Great Slave Lake. Five mills operated in 1941 with a daily capacity of 535 tons. Three of the mills were new.

Yukon's gold output comes almost entirely from placers and is won chiefly from large-scale dredging operations in the vicinity of Dawson City, Klondike district.

Nova Scotia's output is from gold-quartz mines and Alberta's from placer operations. Nova Scotia had two mills in operation, one of which closed late in 1941.

Silver produced in Canada totaled 21,754,798 fine ounces valued at $8,323,603 in 1941 compared with 23,833,752 fine ounces valued at $9,116,172 in 1940. Production is obtained mainly as a byproduct from the treatment of base-metal ores. A substantial amount is also produced from gold-quartz ores and from silver ores; a small amount comes from gold placers.

British Columbia produces nearly half of Canada's silver. The leading silver producer in the Dominion is the Sullivan lead-zinc-silver mine at Kimberley, B. C.

Production of silver in the Cobalt and Sudbury areas in Ontario is important, although production from the Cobalt area has been declining for several years. On the other hand, production from the nickel-copper mines of the Sudbury area has increased. Preliminary figures on the yield in 1941 are 4,981,751 ounces.

Western Quebec has increased its production of silver in recent years owing to rapid development of copper-gold ores, copper-pyrite ores, and gold-quartz ores. Production from Quebec amounted to 1,656,527 ounces in 1941.

Silver production in Manitoba and Saskatchewan comes mainly from the copper-zinc ores of the Flin Flon mine and from a number of smaller properties. The 1941 output from Manitoba is given at 966,102 ounces (preliminary) and from Saskatchewan 2,054,731 ounces (preliminary).

In Yukon silver is produced from silver-lead ores and from gold placers. The 1941 output is given as 1,195,582 ounces (preliminary).

In the Northwest Territories the radium ores in the Great Bear Lake district and the gold ores from several districts produce appreciable quantities of silver. Production from this Province in 1941 was 15,189 ounces. Output in Nova Scotia is small, amounting to 614 ounces (estimated) in 1941.

Newfoundland.—Gold and silver production in Newfoundland depends wholly on the operations of the Buchans Mining Co. at

its lead-zinc-copper mine at Buchans. Output is given at 21,194 ounces of gold and 1,657,342 ounces of silver in 1941, compared with 21,786 ounces of gold and 1,494,066 ounces of silver in 1940.

MEXICO

The Republic of Mexico ranks first among the silver-producing nations of the world. In 1941 Mexico produced 78,363,961 fine ounces, exceeding the United States by more than 7,000,000 ounces and contributing nearly 30 percent of the total world production. Output in 1941 was some 4,000,000 ounces less than in 1940, when 82,640,074 ounces were produced.

The bulk of Mexico's silver comes from the belt of highlands extending southeasterly from Arizona and New Mexico toward Mexico, D. F.; production south of the latitude of Mexico, D. F., is much less important.

Hidalgo was the leading State in silver production in 1941 with a total of 874,111 kg. The mines in the Pachuca district, world-renowned for many years, supplied most of the production. These silver mines are the greatest in Mexico.

Chihuahua ranked next to Hidalgo, with a production of 410,367 kg. in 1941. The most important districts center around Chihuahua and San Francisco del Oro in the central part of the State and around Parral and Santa Bárbara in the southern part.

Zacatecas followed Chihuahua closely in 1941, with 398,771 kg. of silver. About 70 percent of this came from the Fresnillo district in the central part of the State. The next most important district was the Mazapil, in the northeastern part of the State.

The three States, Hidalgo, Chihuahua, and Zacatecas, produced 70 percent of Mexico's silver in 1941. No other State reached the 200,000-kg. mark. San Luis Potosí approached this amount with 186,067 kg.; there are large mines near Charcas, Matehuala, and La Paz. Michoacán produced 158,872 kg., most of which came from the large mine of the American Smelting & Refining Co., at Angangueo. Durango produced 124,281 kg.; the most important district is the San Dimas.

The remaining production of about 250,000 kg. came from a number of other States; Guanajuato and Guerrero together produced about half.

Mexico has never been an outstanding gold producer among the countries of the world. In 1941 the Republic produced 24,882 kg. (799,975 fine ounces). The gold deposits are closely associated with the silver deposits. The six leading States, in the order named, were Hidalgo, Chihuahua, Durango, Michoacán, Zacatecas, and Guanajuato.

WEST INDIES AND CENTRAL AMERICA

Puerto Rico.[8]—Gold and silver mining in Puerto Rico is but little developed. This condition is due to general apathy of Puerto Rican capital toward mining and to the lack of trained mining labor, of roads in many sections of the country, and of plants for treating the ore.

[8] Brief abstract from an article by Ray, Horatio C., Gold Deposits of Puerto Rico Rocks and Minerals, vol. 16, November 1941, pp. 404-405.

Both placer and lode deposits are known on the island, and some development work has been done on them. Nearly all the streams coming from the volcanic backbone of the island carry placer gold, but the amount of gold-bearing gravel is small. Most of the placers are in the general vicinity of Barranquitas-Naranjito-Corozal, Luquillo Forest Reserve, and San German.

Lode deposits have been prospected near Barranquitas, Corozal, and San German and the Carmen township of Guayama. Some of these deposits are considered to have commercial possibilities if systematic development were made and mills were built to concentrate the ore.

Cuba.—Two mines have produced gold or silver in Cuba during the last 10 years. The Delita mine on the Isle of Pines operated for a time in 1937 and produced 1,311 ounces of gold and 2,255 ounces of silver. The Nerva Potosí mine in the Province of Oriente operated regularly in 1941; in 1940 it produced 2,857 ounces of gold.

Dominican Republic.—Production of gold in the Dominican Republic amounted to 636 kg. valued at $546,476 in 1941 compared with 271 kg. valued at $241,987 in 1940. No large companies operate in the republic, as virtually all the gold is produced from numerous small placers. Hand washing of the gravel is still largely used; daily returns are small. Lode deposits are known but have been little developed. No silver is produced in this country.

Nicaragua.—Gold production in Nicaragua has shown a phenomenal rise during the last 10 years. From a value of $382,189 in 1932, production leaped to $7,323,265 in 1941, an increase of about 1800 percent. Silver production also increased from a value of $11,100 in 1932 to $93,553 in 1941, although the value of production in 1940 was $100,149.

The La Luz Mines, Ltd., led in total gold and silver produced in 1941 with 75,047 ounces of gold valued at $2,619,884 and 32,383 ounces of silver valued at $10,988. Next in rank was the Compañia Minera la India with a production of 32,732 ounces of gold valued at $1,134,879 and 41,424 ounces of silver valued at $13,624. Other important producers included the Neptune Gold Mining Co., the San Juan Mines Co., the Compañia Minera del Jabali, the Compañia Minas Matagalpa, and the Empresa Minera de Nicaragua.

Guatemala.—Production of gold in Guatemala during the past 11 years reached a peak in 1931 when 294 kg. were produced. Since 1932 little more than half this amount has been derived in any year, and in 1941 only 78 kg. were produced. This country has no known workable deposits of silver.

Panama.—Production of gold in Panama during the past decade reached its peak in 1934 when 13,895 fine ounces were produced. Since that year, output has steadily declined, except for 1937 when a temporary revival was experienced. Production in 1941 totaled only 2,115 ounces.

The higher production from 1934 to 1937 was due mainly to the development of two mines in gold-quartz veins in the San Francisco and Santa Fe districts in the Province of Veraguas. Operations in these districts ceased in 1937.

Since 1938 most of the gold has come from small placer operations in nearly every territory in the country. Large defense projects in the Canal Zone and inability to get mining machinery are the two

factors responsible for the decline of gold mining in Panama in the last 2 years.

Silver has been of minor importance in Panama; no production has been reported since 1936.

SOUTH AMERICA

Argentina.—Silver production in Argentina amounted to 3,978,400 fine ounces in 1941 compared with 3,242,200 ounces in 1940. Gold in 1940 amounted to 12,860 fine ounces; figures for 1941 are not available. More than half of the gold is produced from placers. Six gold mines have been reported in production, one in the Province of La Rioja, one in the Andes territory, and four in the territory of Neuguén. The silver is largely produced from lead concentrates.

Bolivia.—Bolivia's production of 8,158 fine ounces of gold in 1941 was divided among eight principal producers, of which the Empresa Minera la Joya accounted for about 65 percent of the total. This company produces gold from auriferous pyrites. Five principal producers of silver supplied nearly all of the country's 7,348,695 ounces. Gold and silver mining is being handicapped by lack of ocean transportation of the ore to United States smelters; also, it is not possible to obtain mining equipment from the United States.

Brazil.—In 1941 Brazil produced 147,309 fine ounces of gold from lode mines; no data are available on placers, except that prospectors are still very active along the gold-bearing streams. All but a small part of Brazil's gold comes from the State of Minas Gerais, where there are two important mines. These are the Morro Velho and the Passagem, where the gold occurs in extensive ore shoots along the planes of schistose rocks. The Morro Velho is over 8,000 feet deep.

Some gold is also produced in the States of Paraná, Rio Grande do Sul, São Paulo, Goias, and Maranhão.

Silver production in Brazil is small, amounting to only 21,170 fine ounces in 1941.

Colombia.—Since 1931 the production of both gold and silver has gained steadily in Colombia, and 1941 was the high year for each metal. Of the 656,019 fine ounces of gold produced in 1941, about 60 percent came from placers and 40 percent from lodes. Most of the placer gold is recovered by dredges, eight being in operation in 1941. Hydraulicking was carried on by 60 operators. Two companies produced most of the lode gold, but 53 small operators also reported production.

Colombia's production of 271,115 ounces of silver in 1941 came almost entirely as a byproduct of gold mining

Ecuador.—The 70,264 ounces of gold and the 116,836 ounces of silver produced in Ecuador in 1941 came almost entirely from the operations of two companies—the Cotopaxi Exploration Co. and the South American Development Co. Six other companies carried on exploration work.

Guianas.—Information on the Guianas is almost nonexistent. It is estimated that British Guiana produced about 30,000 ounces of silver in 1941, French Guiana about 35,000 ounces, and Surinam about 12,000 ounces.

Gold production from British Guiana probably amounted to a few thousand ounces. One company working in British Guiana holds about 900 acres of dredging concessions, over 66,000 acres of exclusive permissions, and 3,000 acres of claims. These holdings are centered in the Mahdia, Potaro, Konawaruk, and Essequibo areas. The gravel is stated to carry 2.90 to 5 grains of gold per cubic yard.

Surinam for several years has produced over 400,000 grams of gold annually, all of which has been won from placers by the use of long toms, sluices, and hand pans.

Peru.—Peru, with an output of over 15,000,000 ounces of silver, furnished more than half of the total 28,105,000 ounces produced in South America in 1941.

COPPER

By T. H. Miller and H. M. Meyer

SUMMARY OUTLINE

GENERAL SUMMARY

The inability of copper producers to meet all requirements, evident in the latter half of 1940, was accentuated in 1941. Copper was consumed at an astounding rate in the United States for its own military requirements, for the needs of its Allies, and for civilian uses, exceeding previous records by 40 to 50 percent. A demand of unknown proportions could not be filled. Consumption doubtless would have been much larger had enough metal been available to fabricators for unrestricted use.

The trend of events throughout 1940 and 1941 forced many observers to revise their opinions regarding the adequacy of copper supplies in the United States. When the present World War began, few would have believed that domestic production plus unprecedented imports could fall so far short of satisfying all needs. The British Empire's position as regards copper was then considered relatively satisfactory, and when the tremendous resources of the United States were added, no problem regarding supplies of the metal was generally anticipated. This opinion, of course, held before the United States entered the war and before it was known that this country must supply copper in fabricated form to virtually all the nations at war with the Axis Powers or preparing to resist them. The unbelievable growth in plans for airplanes, tanks, and other munitions made all previous ideas regarding consumption requirements obsolete.

Supply problems.—Early in 1941, as data on military requirements were made public, it became evident that civilian use of copper would have to be drastically curtailed. Defense agencies studied at length the problems of estimated needs and supplies from domestic and foreign mines before copper was placed under mandatory industry-wide control, effective June 1. The order provided for the setting aside of a producers' pool to be allocated by the Director of Priorities and the filling of defense orders, according to preference ratings, before any shipments for civilian use were made. All copper owned by the Metals Reserve Co. on and after June 1 was also to be allocated by the Director of Priorities.

When the order was issued the Director of Priorities announced that the total supply of copper in 1941 was expected to be between 1,340,000 and 1,470,000 tons, whereas total military and civilian

requirements were estimated at 1,810,000 tons, indicating an expected shortage of 340,000 to 470,000 tons. Later in the year the estimates for 1941 were revised, and data for 1942 were added. The new estimates showed that the emergency in regard to copper supplies was growing worse rapidly and foretold more stringent controls on civilian use of copper as the war progressed. This dark outlook prevailed when plans for overwhelming military dominance of the world had not reached their peak. Figures released by the Office of Emergency Management in October are quoted below, in short tons:

	1941	*1942*
Supply:		
Domestic production	950, 000	1, 100, 000
Imports (Latin America)	500, 000	500, 000
Other imports	100, 000	100, 000
Secondary copper	100, 000	100, 000
	1, 650, 000	1, 800, 000
Demand:		
Military [1]	600, 000	1, 000, 000
Essential civilian	400, 000	400, 000
Other civilian	880, 000	1, 170, 000
	1, 880, 000	2, 570, 000

[1] Includes foreign.

The agency explained that the large "other civilian" demands were predicated on the theory of unrestricted consumption to fit in with the rise in national income under the defense program.

Salient statistics of the copper industry in the United States, 1925–29 (average) and 1938–41, in short tons

	Average (1925–29)	1938	1939	1940	1941
New copper produced—					
From domestic ores, as reported by—					
Mines	885, 826	557, 763	728, 320	878, 086	958, 149

[1] Includes old tailings.
[2] Exclusive of Alaska, figures for which Bureau of Mines not at liberty to publish.
[3] Figures not yet available.
[4] Data include copper imported for immediate consumption plus material entering country under bond.
[5] Figures cover 9 months only; data for last quarter of year confidential.
[6] Total exports of copper, exclusive of ore, concentrates, composition metal, and unrefined copper. Exclusive also of "Other manufactures of copper," for which figures of quantity not recorded.
[7] Bureau of Mines not at liberty to publish calculated totals owing to confidential nature of foreign trade data for last quarter of year.
[8] Approximate.

General Preference Order M-9 was amended in July to extend control to copper-base alloys and fabricated products made from copper or from copper-base alloys, such as brass or bronze; and Order M-9-A, issued August 2, placed copper and copper-base alloys under 100-percent priority control.

In an order dated September 30, copper scrap also was placed under full priority control. The order stated that copper ranked next to aluminum as the most difficult of the critical metals to obtain in quantities sufficient for defense and civilian needs. Priority assistance was granted Latin-American copper mines on October 15 to enable them to obtain necessary maintenance materials and operating supplies more rapidly. This action marked another effort to improve the supply-demand situation by helping to increase production in the affected countries.

Amendments and revisions of the conservation orders mentioned above were issued subsequently from time to time, partly to clarify them and to withdraw some unsatisfactory features but mainly to tighten controls further and to restrict unnecessary uses. There have been repercussions among many other metals as a result of the copper-conservation orders. In saving copper, the secondary effect of the orders has been to release large and small quantities of other metals normally alloyed with copper in the restricted uses. The extent of the effects on other metals has been somewhat startling.

Jeffries [1] has prepared a report on copper conservation.

Percy Barbour, in the American Metal Market of September 23, 1941, questioned the accuracy of defense agency data on requirements for war and civilian consumption, contending that they were too high; and Arthur Notman, in a statement reprinted from the New York Sun in Metals, January 1942, was inclined to agree. Barbour pointed out that civilian requirements were calculated by adding wartime to peacetime demand and, in addition, that Army and Navy estimates were well-known to be on the ample side. He also pointed out that the amount of copper available for German consumption during the period of preparation for war, 1933-38, was considerably below half of the estimated requirements of Great Britain and the United States for 1 year.

Price action.—The strain on supplies of copper in 1941 paved the way for sharply increased prices. In deference to the expressed interest of the Office of Price Administration in preventing price advances for this commodity, as well as for others, large producers maintained a price of 12 cents a pound for electrolytic copper, delivered Connecticut Valley, until August 12. For more than 6 months, custom smelters and small producers obtained premiums for nearby metal. On August 12 a ceiling of 12 cents for copper was established by the Price Administrator, and it has remained at that level beyond the time of the preparation of this report (June 1942). This inactivity of prices contrasts directly with the movement of prices in the previous World War. The average quoted price for electrolytic copper, New York, was 13.6 cents in 1914, 17.3 cents in 1915, and 27.2 cents in 1916. An agreement between copper producers and the War Industries Board fixed the maximum price for copper, f. o. b. New York, at

[1] Jeffries, Zay, A Program for Conservation of Copper: One of a series of reports by the Advisory Committee on Metals and Minerals, Clyde E. Williams, chairman, submitted to the Office of Production Management through F. B. Jewett, president of the National Academy of Sciences; reprinted in several technical journals.

23.5 cents a pound on September 21, 1917. This price remained in force until July 2, 1918, when it was advanced to 26 cents.

During the year the Office of Price Administration had been investigating means of encouraging marginal mines to produce copper, lead, and zinc without increasing the prices paid for the bulk of production. Late in 1941 arrangements were made for Government purchase of copper from three Michigan companies at 1 cent a pound above "out-of-pocket" costs. In January 1942 it was announced that the Metals Reserve Co. would purchase copper output above quotas at 17 cents a pound, Connecticut Valley, for 2½ years. Quotas were to be assigned by the Office of Production Management and the Office of Price Administration, and beginning February 1, 1942, production was to be entitled to the premium price. Any metals acquired at premium prices by Metals Reserve Co., which were not used for or by the Government, were subject to allocation to consumers at the ceiling prices fixed by the Price Administrator.

Government purchasing.—As stated in the chapter on Copper in Minerals Yearbook, Review of 1940, arrangements to purchase Latin American copper were begun in the final quarter of 1940, when it became apparent that production in the United States would be inadequate for all requirements. First Government contracts, announced December 19, 1940, totaled 100,000 short tons, distributed among Anaconda Copper Mining Co., Kennecott Copper Corporation, American Metal Co., Ltd. (Cerro de Pasco Co.), and Phelps Dodge Corporation. The 1941 stockholders' report of the Anaconda Copper Mining Co. stated that, beginning March 1941, large quantities of copper produced by their foreign subsidiaries were delivered to Metals Reserve Co. and that, with the exception of comparatively small quantities required for Latin America, the entire output was currently being sold and delivered to that organization. The report stated that the price paid by Metals Reserve Co. was the equivalent of 9½ cents a pound f. a. s. Chilean ports until October 8, when it was advanced to the equivalent of 10¾ cents f. a. s. Chile, applicable to deliveries made during September, October, November, and December. Effective January 1, 1942, the price was increased to 11¼ cents, which, the report stated, was the current price under which foreign production was being delivered to the Government (the report was dated April 11, 1942). The annual report of the Kennecott Copper Corporation stated that the Braden Copper Co. (a Kennecott subsidiary) delivered virtually all of its 1941 production, most of which was fire-refined copper, to the Metals Reserve Co.

In May 1942 Jesse Jones, Administrator of the Reconstruction Finance Corporation, of which Metals Reserve Co. is a subsidiary, stated before the Senate Committee on Banking and Currency that his organization had purchased 760,000 tons of copper from Latin American countries and in addition intended to import metal from New Zealand, Australia, and Africa.

The Government also arranged during the year to acquire metal, belonging to France and other countries, which was stranded in the United States.

In May 1942 the Copper Recovery Corporation was formed to act as agent for the Metals Reserve Co. and to plan for physical transfer and payment for 300,000 tons of copper and brass products saved for military uses by limitation and conservation orders of the War Pro-

duction Board (formerly Office of Production Management). Where possible, the metal was to be used to fill military requirements for shapes and grades in the form in which it was held in inventory. The stocks were expected to yield 255,000 tons of copper and about 45,000 tons of zinc.

Prospects for increased production.—Development of the open-pit copper mine at Morenci, Ariz., begun in 1937, promised an annual production of 75,000 tons of copper a year. The first ore was sent to the Morenci mill in January 1942; the smelter started later, and capacity operations were expected by about July. Following the declaration of war on Japan, a 7-day week was adopted at some large properties that had been operating upon a shorter-week basis. As a result of the longer work period, properties of the Anaconda Copper Mining Co. were expected to yield an additional 24,000 to 36,000 tons of copper a year and those of the Phelps Dodge Corporation 12,000 tons more. The Kennecott Copper Corporation was already upon a 7-day basis. Increased facilities at Inspiration Consolidated were expected to yield another 12,000 tons of copper annually, beginning early in 1942.

Contracts between the Metals Reserve Co. and the Defense Plant Corporation (both Reconstruction Finance Corporation subsidiaries) and mining companies forecast the following annual increments to domestic supply:

	Short tons
Bagdad Copper, Ariz	10, 200
Calumet and Hecla, Mich	1, 250
Gray Eagle Mining, Calif	6, 800
Castle Dome, Ariz	23, 000
National Tunnel & Mines, Utah	5, 000
Phelps Dodge,[1] Ariz	60, 000
	106, 250

[1] Additional at Morenci.

Bonus prices paid by the Metals Reserve Co. for above-quota copper production, already mentioned under the discussion on price action, will contribute an additional unknown amount to domestic supply.

Arizona report on marginal production.—During the year the Arizona Department of Mineral Resources, at the request of the Arizona Copper Tariff Board, prepared a report on the production possibilities of marginal mines in Arizona, which it submitted on August 1 to the Office of Price Administration and Civilian Supply. The report stated that an increase in the price of copper to 14 cents a pound could result in an additional output of 55,000,000 pounds of copper yearly by small mines in Arizona (85,000,000 pounds if the Inspiration Consolidated Copper Co., one of the major producers, is considered) provided a return of the necessary capital investment could be guaranteed. Further advance to 16 cents would bring out an additional 32,000,000 pounds, the report stated, but advances to higher levels would result in less-important gains.

DOMESTIC PRODUCTION

Statistics on copper production may be compiled upon a mine, smelter, or refinery basis. Mine data are most accurate for showing the geographic distribution of production; smelter figures are better

for showing the actual recovery of metal and fairly accurate for showing the source of production; and refinery statistics give precise information regarding metal recovery but indicate only in a general way the source of crude materials treated. The chapter on Copper in Mineral Resources of the United States, 1930, part 1, discusses the differences among the three sets of figures.

Copper produced from domestic ores, as reported by mines, smelters, and refineries, 1937–41, in pounds

Year	Mine	Smelter	Refinery
1937	1,683,996,000	1,669,322,278	1,644,505,129
1938	1,115,525,160	1,124,656,539	1,105,148,323
1939	1,456,639,000	1,425,349,488	1,409,745,816
1940	1,756,172,000	1,818,167,516	1,854,478,996
1941	1,916,298,000	1,932,144,953	1,950,816,680

PRIMARY COPPER

Smelter production.—The recovery of copper by United States smelters from ores of domestic origin totaled 1,932,144,953 pounds in 1941—a 6-percent increase over 1940. Domestic smelter output constituted 51 percent of the world production during 1925–29. The proportion dropped sharply in the succeeding years until 1934, when it was only 17 percent. It rose to 32 percent in 1936 and since then has never fallen below 25 percent, fluctuating between the two figures. The proportion was believed to be close to the higher level of the range in 1940 and 1941 and possibly exceeded it somewhat in the latter year.

The figures for smelter production are based upon confidential returns from all smelters handling copper-bearing materials produced in the United States. For Michigan the sum of furnace-refined copper and copper cast into anodes for electrolytic refining is included. The figures for blister represent the fine-copper content. Some casting and electrolytic copper produced direct from ore or matte is included in the smelter production. Metallic and cement copper recovered by leaching is included in smelter production.

The precise quantity, in pounds, of copper produced by smelters in the United States and its value are shown by years for 1845–1930 in the Copper chapter of Mineral Resources of the United States, 1930, part 1.

Copper produced in the United States from domestic ores, 1937–41, by States

[Smelter output, in pounds fine]

1 Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.

Copper produced (smelter output) in the United States, 1937–41, and total 1845–1941

[Values rounded]

Year	Short tons	Value
1937	834,661	$201,988,000
1938	562,328	110,216,000
1939	712,675	148,236,000
1940	909,084	205,453,000
1941	966,072	227,993,000
Total 1845–1941	28,464,550	8,480,013,000

Mine production.—The figures for mine production are based upon reports supplied to the Bureau of Mines by all domestic mines that produce copper. Details of the method of collecting the statistics and reasons for the discrepancy between mine-, smelter-, and refinery-production figures are given in the Copper chapter of Mineral Resources of the United States, 1930, part 1.

Mine production is more accurate than either refinery or smelter production for showing the distribution of domestic output by States and districts. It also indicates the production by calendar years more exactly, because additional time is required for smelting and refining. Mine production in 1941 was 1,916,298,000 pounds—an increase of 9 percent over that in 1940 and 8 percent above the average for 1925–29.

Production by States and districts.—The following tables show mine and smelter production by States for 1940 and 1941 and mine output by districts for 1937–41. In 1941 Arizona, Utah, and Montana led in production, with 75 percent of the smelter total compared with 73 percent in 1940; adding the output of Nevada, New Mexico, and Michigan to the foregoing brings the proportions to 96 percent of the total for the country compared with 95 percent in 1940. Arizona supplied 34 percent compared with 28 percent for Utah and 13 percent for Montana. Both Arizona and Utah made noteworthy gains in output, and these States contributed a greater proportion of the country's total; Montana's output was relatively unchanged, and its share of the total therefore declined. There was nothing outstanding

among the increases for other producing States; and some States, notably Colorado, California, and Washington, recorded decreases. Comparison of present production with that of the past century shows that Arizona is now producing at about the same rate in relation to the country total as over the entire period 1845–1941; Montana's and Michigan's shares in 1941 (13 and 5 percent, respectively) mark declines from 21 and 16 percent during 1845–1941; and Utah's sharply increased proportion of 28 percent (compared with 13 percent) partly offsets the relative decreases indicated for Montana and Michigan. Nevada and New Mexico are now producing considerably larger proportions of the country's total than in 1845–1941.

Copper produced in the United States, according to smelter and mine returns, by States, 1940–41 and 1845–1941, in short tons

State	1940		1941			1845-1941, smelter output

[2] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[3] Less than 1 ton.
[4] Approximate production through 1928. Figures for 1929–41 confidential and included under "Undistributed."
[5] Less than 0.01 percent.
[6] Includes Tennessee for 1929–41.

In 1941, for the sixth consecutive year, the Bingham (Utah) district was the largest copper producer in the United States; its output was slightly more than double that of Butte (Mont.), for 6 years its nearest competitor and before 1936 usually ahead of Bingham in copper production. Following Globe-Miami (Ariz.), which has ranked third for a number of years, is a group of districts that frequently change places in importance as copper producers.

Details of mine production, by districts and companies, in 1941 are available in the chapters of this volume dealing with the production of gold, silver, copper, lead, and zinc in the various States.

Mine production of copper in the principal districts of the United States,[1] 1937–41 in terms of recovered copper, in short tons

Quantity and estimated recoverable content of copper-bearing ores.—The following tables list the quantity and estimated recoverable copper content of the ore produced by mines in the United States in 1940; figures for 1941 are not yet available. Of the total copper produced from copper ores in the United States in 1940, 84 percent was obtained from ores concentrated before smelting and 11 percent from direct-smelting ores; in addition, copper was recovered from 3,198,904 tons of copper ore treated by straight leaching. The percentages for 1940 compare with 81 percent obtained from concentrated ore (including ores treated by combined leaching and flotation) and 16 percent from direct-smelting ores in 1939. In 1939, 2,114,407 tons of copper ore were treated by straight leaching.

Close agreement between the output as reported by smelters and the recoverable quantity as reported by mines indicates that the estimated recoverable tenor is close to the actual recovery. Classification of some of the complex western ores is difficult and more or less arbitrary. "Copper ores" include not only those that contain 2.5 percent or more copper but also those that contain less than this percentage if they are valuable chiefly for copper. Mines report considerable copper from ores mined primarily for other metals. These include siliceous gold and silver ores, lead and zinc ores, and pyritic ores.

Copper ore, old tailings, etc., sold or treated in the United States in 1940, with copper, gold, and silver content in terms of recovered metals

State	Ore, old tailings, etc., sold or treated (short tons)	Copper produced: Pounds	Copper produced: Percent	Gold produced (fine ounces)	Silver produced (fine ounces)	Value of gold and silver per ton of ore

[2] Exclusive of Alaska, figures for which Bureau of Mines not at liberty to publish.

REFINERY PRODUCTION

The refinery output of copper in the United States in 1941 was made by 10 plants; 8 of these employed the electrolytic method and 2 the furnace process on Lake Superior copper.

There are five large electrolytic refineries on the Atlantic seaboard, three Lake refineries on the Great Lakes, and three refineries west of the Great Lakes—one at Great Falls, Mont.; one at Tacoma, Wash.; and one at El Paso, Tex. Of the above plants, the Lake refinery of the Quincy Mining Co. has been idle since 1933.

In addition to the foregoing plants, that at Inspiration, Ariz., is equipped to make electrolytically refined copper direct from the liquors obtained from leaching; this copper is shipped as cathodes to other refineries, where it is melted and cast into merchant shapes.

The 12 plants indicated constitute what commonly are termed "regular refineries." Of these plants, 9 employ the electrolytic process and 3 the furnace process. The electrolytic plants have a rated capacity of 1,561,000 tons of refined copper a year. As they produced 1,445,000 short tons in 1941, this part of the industry was operated at 93 percent of capacity.

Early in June 1942, the Phelps Dodge Corporation announced the letting of a contract for expansion in its electrolytic plant at El Paso. The cost was reputed to be $2,650,000, and plans were reported to include a 50-percent increase in capacity of furnace and tank house. The increased capacity is required to take care of expansion in mine and smelter production at Morenci, Ariz.

The following tables show the production of refined copper at regular refining plants, classified according to source, grade, and form in which cast.

Primary and secondary copper produced by regular refining plants in the United States and imported, 1937–41, in pounds

	1937	1938	1939	1940	1941
Primary:					
Domestic:[1]					
Electrolytic[2]	1,548,857,307	1,032,976,656	1,324,817,430	1,767,219,614	1,859,421,387

Total new refined copper made available	2,148,602,618	1,588,434,754	2,051,558,228	2,763,786,187	(5)
Secondary:					
Electrolytic[6]	312,831,103	185,084,601	233,225,695	235,337,792	190,873,847
Casting	380,000				8,476,000
	313,211,103	185,084,601	233,225,695	235,337,792	199,349,847
Grand total	2,461,813,721	1,773,519,355	2,284,783,923	2,999,123,979	(5)

[1] The separation of refined copper into metal of domestic and foreign origin is only approximate, as an accurate separation at this stage of manufacture is not possible.
[2] Some copper from Michigan is electrolytically refined at eastern refineries and is included as electrolytic copper.
[3] Data include copper imported for immediate consumption plus material entering country under bond.
[4] Figures cover January to September, inclusive. Data for last quarter not available for publication.
[5] Bureau of Mines not at liberty to publish, owing to confidential nature of import figures for last 3 months of year.
[6] Includes some secondary Lake copper.

Copper cast in forms in the United States, 1940–41

Form	1940		1941	
	Pounds	Percent	Pounds	Percent
Wire bars	1,245,000,000	43.50	1,472,000,000	49.23
Cathodes	906,000,000	31.66	601,000,000	20.10
Cakes	293,000,000	10 24	383,000,000	12.81
Ingots	175,000,000	6.11	257,000,000	8.60
Other forms	243,000,000	8 49	277,000,000	9.26
	2,862,000,000	100.00	2,990,000,000	100.00

In addition to the regular refineries, numerous plants throughout the country operate on scrap exclusively, producing metallic copper and a great variety of alloys. The output of these plants is not included in the statements of refined-copper production in the preceding tables but is included in the following statement of secondary-copper production.

Copper sulfate.—The production of hydrous copper sulfate or bluestone by copper refineries in the United States was 54,833,327 pounds having a copper content of 13,967,000 pounds in 1941 compared with 44,308,107 and 11,286,000 pounds, respectively, in 1940. The output of copper sulfate by plants other than the regular primary refineries was 116,143,533 pounds with a reported copper content of 29,368,000 pounds in 1941 compared with 89,723,720 pounds containing 22,808,000 pounds of copper in 1940.

SECONDARY COPPER

Secondary copper includes material recovered from remelting old copper and copper scrap and from the treatment of copper alloys or alloys treated without separation of the copper. The following table summarizes the production of secondary copper during 1937–41. Further details appear in the chapter on Secondary Metals—Nonferrous.

Secondary copper produced in the United States, 1937–41, in short tons

	1937	1938	1939	1940	1941
Copper as metal	285,600	192,400	151,370	170,839	135,869
Copper in alloys	246,500	167,400	[1] 348,330	[1] 361,207	[1] 590,527

[1] Includes copper in chemicals as follows: 1939, 3,200 tons; 1940, 9,431 tons; 1941, 9,804 tons.

CONSUMPTION AND USES

NEW SUPPLY

The usual discussion on supplies of new copper available for domestic use can be given in general terms only. This condition is due to the fact that precise information in 1941 regarding additions to supply by importation and withdrawals from supply for exportation are

available for the first 9 months of the year only; data for the last quarter are confidential. A tremendous gain in imports and a severe drop in exports, however, are shown by the 9-month totals. Enough data are at hand to indicate that new copper was withdrawn from supply for domestic consumption in 1941 at a considerably higher rate than ever before. The record consumption, of course, was a direct result of the present World War, in which, however, the United States did not become an active participant until December 1941. The entry of this country into the war and the successive announcements of new and larger armament plans foretell new consumption records in 1942 and 1943. The recording of these tonnages as domestic consumption is accurate only insofar as consumption applies to the use of refined copper and primary fabricated shapes. Much of the metal, particularly in 1940 and 1941, actually was used in foreign countries, for after its manufacture here into war and industrial products it was or will be shipped abroad.

The following table shows the computation of apparent domestic consumption of new copper for 1937 to 1940. It should be noted that exports and stocks include some refined secondary copper that cannot be determined separately and that actual consumption of new copper would differ from the figures shown in the table by the changes in consumers' stocks.

New refined copper withdrawn from total year's supply on domestic account, 1937–41, in pounds

	1937	1938	1939	1940	1941
Total supply of new copper	2,148,602,618	1,588,434,754	2,051,558,228	2,763,786,187	(1)
Stock at beginning of year	220,000,000	358,000,000	362,000,000	191,000,000	183,000,000
Total available supply	2,368,602,618	1,946,434,754	2,413,558,228	2,954,786,187	(1)

[1] Bureau of Mines not at liberty to publish, owing to confidential nature of foreign trade figures for last 3 months of year.
[2] Includes refined copper in ingots, bars, rods, or other forms.
[3] Figures cover January to September, inclusive.

INDUSTRIAL USE OF COPPER

The annual figures of the American Bureau of Metal Statistics on consumption of copper, by uses, for 1937 to 1941, inclusive, are shown in the following table. No other similar data are available in as complete detail. Figures for 1941 confirm the indications that consumption in that year towered above all previous annual totals—it was 50 percent above 1940 and 38 percent above the previous record established in prosperous 1929. Before the war began in 1939, the possibility of again equaling the 1929 record appeared to be reserved for the very distant future. The magnitude of the program for tanks, ships, and airplanes, among other things, quickly changed previous ideas regarding requirements for copper.

The American Bureau of Metal Statistics Year Book states that the absence of information as to uses by arsenals, navy yards, and

shipbuilding yards, and on exports of manufactures (except for the first 9 months of the year) makes it impossible to supply 1941 estimates for all lines. The Year Book says—

The total deliveries of refined copper into consumption in the United States in 1941 (as to which we regard deliveries for manufactures for export as for domestic consumption) were 1,605,000 tons in shipments ex copper and brass mills, wire and cable mills, and in consignments to foundries for the manufacture of brass castings. It does not follow that this delivery passed into use and probably it did not.

Estimated use of copper in the United States, 1937–41, in short tons

Use	1937	1938	1939	1940	1941
Electrical manufactures [1]	212,000	150,000	185,000	247,000	393,000
Telephones and telegraphs	40,000	30,000	39,000	49,000	78,000
Light and power lines [2]	83,000	62,000	67,000	74,000	94,000
Wire cloth	6,800	6,000	8,000	9,200	13,000
Other rod and wire [3]	102,000	60,000	95,000	120,000	253,000
Automobiles [4]	112,000	55,000	85,000	103,000	112,000

Other uses [10]	66,600	46,200	67,600	81,500	
Manufactures for export	45,000	38,800	51,900	148,400	
	860,000	608,000	801,000	1,070,000	1,605,000

[1] Generators, motors, electric locomotives, switchboards, light bulbs, etc.
[2] Transmission and distribution wire and bus bars, accounting only for public-utility companies.
[3] Includes industrial wire and cable, wire in buildings, railway cars and ships, radio broadcasting, railway and municipal signaling, railway electrification, trolley wire, rod and wire for Government projects, blasting wire, flexible cord, and sundries.
[4] Does not include starter, generator, and ignition equipment.
[5] Excludes electrical work.
[6] Bearings, bushings, lubricators, valves, and fittings.
[7] Includes air conditioning.
[8] Excludes electrical equipment.
[9] Other than railway.
[10] Includes condenser tubes, oil-burner tubing, welding rod, screw-machine products, nickel-silver and phophor-bronze products, rivets and burrs, toilet pins, eyelets and grommets, electrotyping and engraving sheet, spark plugs, inner-tube valve stems, jar tops and rouge boxes, flashlight tubes, kerosene lamps, kitchen utensils, kitchen-range boilers, linotype matrices, safety razors, blasting caps, asbestos textiles, water meters, thermostats, soldering coppers, yacht fittings, coinage, washing machines, household water heaters, fire extinguishers, pumps, airplanes, engines, and sundry machinery, etc., all reckoned in terms of copper content.

STOCKS

The following table gives domestic stocks of copper as reported by primary smelting and refining plants. Stocks of blister and anode copper in transit from smelters to refineries are included under blister copper.

Stocks of copper at primary smelting and refining plants in the United States at end of year, 1937-41, in pounds

Year	Refined copper	Blister and materials in process of refining [1]	Year	Refined copper	Blister and materials in process of refining [1]
1937	358,000,000	428,000,000	1940	183,000,000	486,000,000
1938	362,000,000	466,000,000	1941	155,000,000	479,000,000
1939	191,000,000	520,000,000			

[1] Includes copper in transit from smelters in the United States to refineries therein.

Inventories of refined copper at primary refineries in the United States at the end of 1941 were 15 percent below 1940 and were the smallest recorded since 1928. The demand that carried stocks to 114,000,000 pounds at the close of 1928, however, was the industrial boom of that period and varied greatly from the requirements for the war expansion program of 1941. Stocks of blister and anode copper at smelters, in transit to refineries, and at refineries at the end of 1941 were only slightly lower than in 1940 and, on the whole, were of relatively the same size as inventories of this class for a number of years.

Figures compiled by the Copper Institute and published in the press show that domestic stocks of refined, duty-free copper totaled 75,564 tons at the close of 1941 compared with 142,772 tons in 1940. Study of the monthly changes in stocks in 1941 fails to reveal a complete story, inasmuch as free movement of metal was impossible during more than half of the year. The low point of the year in stocks occurred at the end of September, when 63,670 tons were reported. Differences are always found between stock data supplied by the Bureau of Mines and those of the Copper Institute and are due partly to a somewhat different coverage and to an arbitrary but permissible method used by the Copper Institute in designating the copper as domestic or foreign metal. Exceptional conditions in the market during 1941 brought the two sets of figures for the end of that year into closer agreement than usual.

Fabricators' statistics in 1941, published in the press, clearly show the effects of the tremendous demands for copper in that year. Stocks of refined copper in fabricators' hands fell from 339,755 tons at the end of 1940 to 292,973 tons at the end of 1941. Meanwhile, unfilled purchases of refined copper by fabricators from producers were 326,269 and 241,335 tons, respectively. Fabricators' working stocks, which rise and fall according to plant activity, were 237,105 tons on December 31, 1940, and 291,515 tons on December 31, 1941. Unfilled sales by fabricators to customers rose from 413,388 to 547,468 tons, respectively, at the close of 1940 and 1941. The excess of fabricators' stocks over booked orders declined from 15,531 tons at the end of 1940 to —304,675 tons at the end of 1941; this position had worsened further to —425,286 tons by the end of April 1942. Unfilled orders at the end of April 1942 had reached the staggering total of 632,474 tons.

PRICES

Reports to the Bureau of Mines from copper-selling agencies indicate that 1,139,000 short tons of copper were delivered to domestic and foreign purchasers (excluding deliveries to the Metals Reserve Co.) in 1941 at an average price (f.o.b. refinery) of 11.8 cents a pound, compared with 11.3 cents in 1940, 10.4 cents in 1939, and 9.8 cents in 1938.

Average quoted prices for 1940 and 1941 were almost identical with the delivered prices of the Bureau of Mines, each showing an increase of ½ cent a pound in 1941. The two sets of figures are

commonly in slight disagreement, owing to the fact that one is upon a sales basis and the other upon a delivery basis. Moreover, Bureau of Mines compilations of average values are computed upon the basis of weighted deliveries, whereas trade quotations are averages of averages.

Throughout the year primary producers maintained a price for electrolytic copper (delivered Connecticut Valley points) of 12 cents a pound. For much of the year their action was voluntary, in deference to wishes of the Price Administrator that a uniform 12-cent price for copper be maintained. On August 12, however, a ceiling of 12 cents a pound, Valley, was placed on copper by the Office of Price Administration, and it has continued in effect beyond the time this report was prepared (June 1942). The 12-cent ceiling applied to electrolytic-grade copper in the shape of wire bars or ingot bars delivered in carlots. Lake copper, which had previously sold at a slight premium, was placed upon the same basis as electrolytic at Connecticut Valley points. A top price of 11¾ cents a pound, Valley, was set for casting copper made by fire-refining to a standard of 99.5 percent pure, including silver as copper. The casting-copper ceiling was revised to 11¾ cents, f. o. b. refinery, early in September.

Premiums ranging from ¾ cent to 2 cents a pound were allowed for less-than-carlots sold by other than refiners or producers.

The price order exempted sales of copper to the Metals Reserve Co. This provision was made to permit the purchase by that organization of high-cost copper production at higher than ceiling prices. Other provisions referred to other kinds, grades, shapes, or forms, to contracts entered into prior to the order, and to other items.

Later in 1941 the Price Administrator announced that the proposed sale of high-cost Michigan copper to the Procurement Division of the Treasury Department at 1 cent a pound above "out-of-pocket" costs was undertaken with the full knowledge of his agency. Contracts were signed subsequently. An amendment issued January 14, 1942, provided, among other things, that sale above ceiling levels could be made to any Government department, agency, or corporation previously approved in writing by the Office of Price Administration.

Commodity Exchange, Inc., informed the Office of Price Administration and Civilian Supply that with electrolytic copper selling at no more than 12½ cents, Connecticut Valley, the proper relative price for "Standard" copper on the futures market should be approximately 11½ cents. The price agency announced on May 5 that the Commodity Exchange had agreed not to permit the opening up of new positions in the futures market for "Standard" at prices higher than 11½ cents.

The board of governors of Commodity Exchange, Inc., suspended copper trading on July 22 until further notice. This action was attributed to the allotment and priorities orders and regulations of the Office of Production Management in connection with the sale and distribution of copper, which prevented copper deliveries being freely made against Exchange contracts.

Average monthly quoted prices of electrolytic copper for domestic and export shipments, f. o. b. refineries, in the United States and for spot copper at London,[1] 1940–41, in cents per pound

With the market under strict controls, totals for domestic copper sales in 1941 declined from 1940– 1,037,900 tons from 1,109,749 tons. Peak monthly sales occurred in January, when they totaled 104,835 tons, considerably less than half the 254,277 tons attained in September 1940, the highest monthly sales ever recorded.

Transactions on the London Metal Exchange were suspended at the beginning of the war. The maximum buyers' price on standard copper was fixed by the British Ministry of Supply at £62 per long ton in December 1939 and has remained there to the present.

FOREIGN TRADE [2]

Ordinarily United States imports and exports of copper constitute a well-balanced trade through which the smelting, refining, and manufacturing facilities of this country are utilized to treat foreign raw materials and to return copper and manufactures of copper abroad. Normal trade conditions are nonexistent at present (June

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

1942), and many of the avenues of trade are greatly changed. Nonetheless, record-breaking quantities of copper entered the United States in 1941, and large amounts were exported. Exports, however, were in even further stages of manufacture than usual—forms not covered by this report—and they were highly concentrated, no doubt, among what are now the Allies of the United States. For more than a year, the accent in the United States has been on obtaining increased quantities of crude and refined copper for its own expanded needs and for the manufacture of forms suitable for the war needs of nations fighting the Axis Powers.

Beginning with October 1941 all foreign trade information has been held confidential, so data for 9 months only are published in this report. The quantity of crude and refined copper entered during the 9 months, however, was large enough to top all previous annual totals. Meanwhile, exports of refined copper and primary fabricated shapes had declined so far that they were almost the smallest of the century, surpassing the totals for 1933, 1932, and 1901 only.

In 1941 (9 months), 58 percent by weight of the copper imported was contained in ore, concentrates, and unrefined furnace products, and 42 percent was refined copper. These proportions marked an important change from the pre-war years since enactment of the tariff in 1932, when little refined copper was entered. Less than 1 percent of the copper imported in unmanufactured form during 1938 (only 5 percent during 1939) was refined copper. It had become evident by 1940 that metal available in the United States would be inadequate to fill industrial requirements in this country, plus the sharply expanded demands of foreign countries for war products made to a large or small extent of copper. The ratio of refined imports to the total rose to 14 percent in 1940 and, as already pointed out, to 42 percent in 1941. Most of the refined copper brought into the country during 1941 was metal contracted for by the Metals Reserve Co., as mentioned in the opening section of this report.

Virtually all the copper exported is composed of refined metal and primary fabrications therefrom; 97 percent of the total for the first 9 months of 1941 consisted of such forms.

Separation of total exports to show the quantity of domestic copper shipped from the United States is not possible. From enactment of the present tariff until 1940, total exports of refined copper and primary fabricated shapes exceeded imports of unmanufactured copper. In 1940, however, the import excess was 127,000,000 pounds and for the first 9 months of 1941 reached the enormous total of 834,000,000 pounds. The apparent import excess would be reduced substantially if data were available covering copper contained in exports of such manufactured products as airplanes, tanks, and electrical apparatus.

IMPORTS

Although data in 1941 for only 9 months are available for publication, the establishment of a new high record for imports of unmanufactured copper in that year is evident, as imports for 9 months were 7 percent above the previous annual peak in 1940. The main reason for this sharp increase is the enormous gain in receipts of refined copper from Chile. For a number of years before 1940, entries of refined copper comprised no more than 5 percent of the total, but

they represented 42 percent in the first 9 months of 1941. This shift was due to the unprecedented requirements for copper in the United States in 1941 and to the disrupted state of ocean transportation; both of these caused the United States to absorb metal that normally would have been exported to Europe. Other trends are not so evident from the incomplete import figures. Conservation of cargo space probably caused a drop in receipts of ore and resulted in no increase, at least, in receipts of concentrates. Imports of ores, concentrates, and blister copper from British Africa decreased notably in 1941, but imports of crude copper from Belgian Congo appeared to have more than held their own. Canada increased its shipments of both crude and refined copper to the United States. Incomplete data indicate that receipts of concentrates from Newfoundland and blister copper from Peru declined notably in 1941.

Copper (unmanufactured) imported into the United States in 1941 (January to September, inclusive), by countries, in pounds [1]

Country	Ore (copper content)	Concentrates (copper content)	Regulus, black or coarse copper, and cement copper (copper content)	Unrefined black blister and converter copper in pigs or converter bars	Refined in ingots, plates, or bars	Old and scrap copper, fit only for remanufacture, and scale and clippings

[1] Data include copper imported for immediate consumption plus material entering country under bond.
[2] Less than one-half million pounds.

Copper (unmanufactured) imported [1] *into the United States, 1937–41*

Year	Pounds	Year	Pounds
1937	559,749,133	1940	982,684,647
1938	504,327,779	1941 (Jan.–Sept.)	1,049,948,570
1939	672,594,122		

[1] Data include copper imported for immediate consumption plus material entering country under bond.

EXPORTS

Total exports of copper as refined metal and in primary fabricated shapes slumped sharply, according to the incomplete foreign trade data available for publication for 1941; they were surpassed by all but 3 years of the present century. The foregoing statement gives a partial picture only, because huge demands for manufactured products that contain copper caused the shipment of considerable but unknown quantities of this metal from the United States.

Comparison of export data for the first 9 months of 1941 with those for the similar period of 1940 reveals some drastic changes. The largest export class—refined copper in ingots, bars, etc.—declined 78 percent during the 1941 period. Other important decreases were 52 percent for pipes and tubes, 41 percent for rods, and 37 percent for old and scrap. Plates and sheets moved against the general trend and increased 7 percent. Bare-wire exports were 30 percent lower during the first 9 months of 1941 than in the same months of 1940, and rubber-covered wire was 68 percent lower. Weatherproof wire, however, gained 30 percent in the 9-month period of 1941 and the vastly more important "other insulated wire," 84 percent.

Information concerning the destination of exports in 1941 has been published for only the first 3 months of the year. It is a noteworthy and bitter fact that from 1937–40, inclusive, Japan received more of the copper shipped from the United States than did any other country. This movement was halted in 1941, but not before large quantities of metal had been sent to Japan. Germany, France, Italy, and other European countries normally were markets for large quantities of United States copper but naturally are receiving none at present. The United Kingdom was the destination of the second-largest amount in 1940 and doubtless outranked all other countries in 1941.

In recent years, exports of copper and primary manufactures thereof to Brazil and Argentina have increased. Shipments to China gained notably in 1940 and continued to be large during the first 3 months of 1941.

The second table following shows the destinations of copper exported in 1937 to 1940, inclusive, and in the first 3 months of 1941.

Copper exported from the United States, 1937–41, by classes

Class	1937		1938		1939	
	Pounds	Value	Pounds	Value	Pounds	Value

[2] Exclusive of ore, concentrates, and composition metal, exclusive also of unrefined copper, figures for which are not separable from those for ore and concentrates

[3] January to September, inclusive

The value of brass and bronze exported from the United States gained sharply in 1940, when it was five times that in 1939. It declined in 1941; but the total for the first 9 months was larger than any annual total (except 1940) since 1918. Data covering this class, too, are incomplete for publication, but the figures that may be published indicate that the drop in 1941 was shared by all major classes of brass and bronze.

WORLD ASPECTS OF COPPER INDUSTRY

Nothing much can be added to the world discussions given in chapters of this series for several preceding years, as few new data on foreign sources have been made available. The year 1941 witnessed extension of German control over European sources (with Russia the principal exception) of copper and other materials, and authorities testified to Germany's inadequacy as regards copper at least. The more surprising deficiency in copper supplies, however, was that of the United States, which has huge reserves of its own and has access to additional large sources in the Western Hemisphere and elsewhere but whose consumption for nonessential use had to be drastically curtailed to conserve metal for war requirements. The stringent situation in the United States resulted primarily from efforts of this country to fulfill its promise to serve as the arsenal of democracy. The United States did not enter the war until December. However, other democratic powers, chiefly the British Empire, made enormous demands on the United States for supplies of war materials.

Available data on foreign countries are shown in the following pages.

World mine and smelter production of copper, 1938–41, in metric tons

[1] Data not available.
[2] Copper content of blister produced.
[3] According to Year Book of American Bureau of Metal Statistics.
[4] Smelter output from domestic and foreign ores, exclusive of scrap Production from domestic ores only, exclusive of scrap, was as follows 1938, 510,133 tons, 1939, 646,524 tons, 1940, 824,703 tons, 1941, 876,101 tons
[5] Copper content of exports
[6] Figures represent blister copper only In addition to blister copper, Belgium reports a large output of refined copper which is not included above as it is believed produced principally from crude copper from Belgian Congo and would therefore duplicate output reported under the latter country.
[7] Approximate production.
[8] Exclusive of material from scrap.
[9] Smelter output from ores
[10] Output from U S. S. R. in Asia included under U S S. R in Europe
[11] Smelter product.
[12] Exports of ingots and slabs.
[13] Less than 1 ton.
[14] January to August, inclusive.

REVIEW BY COUNTRIES

Australia.—The pressing need for copper for defense purposes in Australia led the Commonwealth Prices Commissioner to raise the refined copper price to £86 10s. per ton in midyear as an inducement toward increased production. At about the same time, the Minister for Supply and Development appointed a committee to investigate copper and bauxite resources. Australia was reported to be partly dependent on overseas sources for copper and entirely dependent for bauxite.

Production figures are not available for 1941, but 22,680 metric tons were produced at smelters in 1940 compared with 20,219 in 1939. Output is mainly from Mount Lyell, Tasmania, and Mount Morgan, Queensland. At the annual meeting of the Mount Lyell Mining & Railway Co., Ltd., on December 12, it was stated that larger tonnages of ore were handled during the year but that, owing to lower copper content, the copper output was a little less.

The Commonwealth Government advanced £10,000 to Mount Morgan, Ltd., for the unwatering and development of the Great Fitzroy mine at Mount Chalmers near Rockhampton. The annual capacity for production was expected to be 2,000 tons. The Government also advanced £50,000 to Mount Isa Mines, Ltd., Queensland, which produces silver, lead, and zinc, so that it may develop copper ore at the mine. It was reported that annual production probably would reach 5,000 tons. Additional prospecting and development work were in progress on other parts of the continent.

Belgian Congo.—Available data on production of copper in Belgian Congo indicate a sharp increase in activity there. Smelter output was estimated at 165,000 metric tons in 1941 compared with 148,619 tons in 1940. As indicated in the preceding report of this series (Minerals Yearbook, Review of 1940, p. 108), the Belgian and British Governments reached an agreement early in 1941 for the delivery of 126,000 metric tons of copper to the United Kingdom by Union Minière du Haut Katanga. The overrunning of Belgium by the Germans had increased the quantities of Belgian Congo copper available to the British and actually made all of it available to enemies of Germany. At the annual meeting of Union Minière du Haut Katanga (May 1941), the company capacity to produce copper was reported as 200,000 tons. New prospecting was then reported to have substantially increased ore reserves. Figures covering imports of copper into the United States during the first 9 months of 1941 show that about 28,600 metric tons of regulus, black or coarse copper, and cement copper and 24,900 tons of unrefined black blister and converter copper were received from Belgian Congo during that period; data covering all of 1941 are not available for publication.

Brazil.—Occurrences of copper in Brazil and recent attempts to promote production there are described in the Foreign Minerals Quarterly of July 1941, issued by the Bureau of Mines.

Canada.—Statistics on mine production of copper in Canada are confidential for both 1940 and 1941. There seems little reason to question, however, that new annual peaks were reached each year. There were noteworthy consumption gains also in 1941, as Canadian industry assumed a larger share in supplying the increasing war needs of the British Empire for fabricated products. The Northern

Miner (Toronto) in its annual number (November 13, 1941) stated that Canada probably was now consuming one-third of its annual output. Large amounts of brass are being manufactured, the review said, and the upward trend will be increased in the current year. The annual review number of the Engineering and Mining Journal for 1941 reported that

Munitions have become the big business of the Dominion and in securing adequate supplies of nickel, copper, and zinc for war effort, along with gold that will maintain credit with the United States, the national economy has been turned over to two agencies that have absolute authority. These are the Department of Munitions and Supply, which is the supreme purchasing control, and the Wartime Prices and Trade Board, which sets prices and wages throughout the land. The Metals Controller, who is working under this closely integrated program, is the arbiter of mining.

The Dominion Bureau of Statistics reported that Canadian base-metal mines, smelters, and refineries worked to capacity during 1941. Plans to produce other metals of strategic importance, in addition to maximum outputs of copper, lead, and zinc, were in evidence.

More than half of the copper produced in Canada in 1941 probably came, as usual, from the nickel-copper mines of the Sudbury district. The principal producer in that area is The International Nickel Co. of Canada, Ltd. This company reported that war requirements dominated markets for its products during the year and that, with few exceptions, all deliveries were made in Canada, the British Empire, and the United States. In past years the company has refined the major part of its copper and exported the remainder as matte. Quebec normally ranks as the second most important Province in copper production. Noranda Mines, Ltd., is the outstanding producer, and others include Waite Amulet, Aldermac Mines, Ltd., and Normetal Mining Corporation, Ltd. All of Quebec's production is refined at Montreal East by Canadian Copper Refineries, Ltd., subsidiary of Noranda Mines, Ltd., which was operated at capacity during the year. The Britannia Mining & Smelting Co., subsidiary of the Howe Sound Co., at Howe Sound, and the Granby Consolidated Mining, Smelting & Power Co., which operates the Copper Mountain mine at Allenby, are the principal copper producers in British Columbia. Copper reserves at the Copper Mountain mine have been greatly amplified in recent years, according to the Canadian Mining Journal of September 1941. Several years ago it was reported that ore reserves might be estimated at 10,000,000 tons. At present, the journal stated, after several years of full-blast operations reserves are estimated at 17,220,729 tons, and current operations were disclosing new ore in excess of the quantity mined. The larger reserves contained an average of 1.32 percent copper, or less than was formerly estimated. Concentrates from the two British Columbia mines mentioned go to Tacoma, Wash., for smelting and refining. The copper produced in Manitoba and Saskatchewan comes from the Flin Flon mine of the Hudson Bay Mining & Smelting Co., Ltd., and the Sherritt Gordon mine of the Sherritt Gordon Mines Co., Ltd. The report of the Hudson Bay Co. for 1941 stated that production of copper, zinc, gold, and silver in that year was the highest on record. The Sherritt Gordon production, which is restricted by current milling capacity, goes to the United States under bond for treatment.

497779—43——10

Chile.—The urgent world need for copper for war purposes gave impetus to production in Chile and output there reached unprecedented levels in 1941; production amounted to 453,594 metric tons compared with 336,861 tons in 1940 and 396,444 tons in 1937, the previous record year. There seems little doubt that Chile, in 1941 as usual, ranked second in importance among the copper-producing countries of the world by a substantial margin, although data for Canada and Northern Rhodesia are not available.

The strain on producers to supply requirements in 1941 marked sharp reversal of the condition that prevailed early in the war period. Then Chile was virtually cut off from its principal markets in Europe, and the large, low-cost output from its mines was almost without outlet.

According to Knox,[3] engineers have been careful to speed up Chilean production and at the same time to avoid certain errors made during the first World War, when frenzied stripping of ore often left the workings so unstable that subsequent operations were hampered.

Japan tried to obtain increasingly large supplies of crude and refined copper from Chile during 1941. Action of the Metals Reserve Co. in contracting to receive most of the copper produced in Latin America not only increased supplies of this metal available to the United States but withheld them from Japan. Reports indicated that 209,403 metric tons of electrolytic copper and 195,861 tons of standard went to the United States in 1941, out of totals of 240,707 and 199,264 tons, respectively, for all countries; Japan received 12,771 and 3,403 tons. Other South American countries received increased amounts of Chilean copper in 1941—Argentina took 10,251 tons and Brazil 8,020 tons of electrolytic copper. Italy was the destination of 6,483 tons of electrolytic copper and 11,990 tons of standard copper exported from Chile in 1940 but could not obtain any in 1941.

The Chile Copper Co. produced 216,847 metric tons of copper in 1941 compared with 150,994 in 1940, and Andes Copper Co. 94,243 tons compared with 72,932; these two companies are Anaconda Copper Mining Co. subsidiaries. The Braden Copper Co. (subsidiary of the Kennecott Copper Corporation) produced 131,703 tons in 1941 compared with 109,185 tons in 1940.

Cuba.—Production of copper in Cuba totaled only 9,838 metric tons in 1941, a decline from 10,500 tons in 1940 and only two-thirds of the output of 14,431 tons in 1938, the peak period of recent years. Minas de Matahambre, Pinar del Rio Province, has been the principal copper-producing property in Cuba. The 1941 annual report of the American Metal Co., Ltd., which owns a 59-percent interest in the Matahambre mine, stated that it had been impossible for some time past to replenish ore reserves as rapidly as ore was extracted. Unless continued search resulted in the development of new ore bodies, the report continued, the mine probably would have to cease production in about a year.

Germany.—Although Germany had overrun most of Europe (except Russia) by the end of 1941 and had access to all of Europe's copper except that of Russia, additions to supply from European mines to offset losses from Germany's major sources of supply overseas were noteworthy only insofar as the Bor mine in Yugoslavia was

[3] Knox, Newton B., South America. Eng. and Min. Jour., vol. 143, No. 2, p. 67.

concerned. Germany's supplies of copper were described in the two preceding chapters of this series. Refined metal, metal products, and scrap materials requisitioned in conquered territory have made substantial though unmeasurable additions to Germany's inventories of copper. Despite these acquisitions in 1940 and 1941, however, all authorities appear to agree that copper is one of the commodities that in the long run will present a serious problem to the Axis Powers; Italy is in a worse position than Germany, and Japan as well lacks adequate sources of supply. Germany's annual deficiency in copper and the rate at which it must draw on stocks of unknown size have been subjects of much speculation. The Metal Bulletin [4] caloulated the current rate of consumption at perhaps 372,000 tons and stated that if deductions of total mine output of 120,000 tons (all accessible Europe), process scrap of 75,000 tons (calculated upon the basis of 20 percent of current output of products), imported scrap of 30,000 tons, and possible war scrap of 25,000 tons were made, an annual drain of 122,000 tons on inventories is indicated. The Mining Journal (London),[5] after estimating current quantities of copper available from every source as compared with former supplies, stated: "From whatever angle the situation is examined. one fact is evident, Germany must replace the equivalent of about 200,000 tons of imported copper (ingots, ores, etc.) to meet even peace-time annual consumption." Percy Barbour [6] stated that Hitler consumed only 1,352,700 metric tons in the 6 years 1933-38 when he was building his war machine. Barbour's article quotes figures showing that Germany, plus all other Europe, except Russia, produced 114,000 metric tons of copper in 1940 and that consumption in Germany plus all other Europe except Russia totaled 771,000 tons in 1939, the latest year for which data are available.

Mexico.—Mine production in Mexico was carried on at a high rate in 1941; the output—48,716 metric tons—was the largest annual total since 1931. In the period 1923-31, however, tonnages produced ranged from 50,062 to 86,554 tons and averaged 61,700 tons. Smelter recovery was reported as 40,914 metric tons in 1941 compared with 31,252 tons in 1940.

Northern Rhodesia.—Northern Rhodesia is another of the large copper-producing countries of the world that have been regularly establishing new annual production records. Mine data for 1940 and 1941 are confidential, but there is no reason to doubt that the uptrend continued in those years as copper was urgently needed to help fill the large war requirements of the British Empire. There have been complaints from time to time that the British excess profits tax has worked a hardship, particularly on some of the companies, and has had a somewhat deterrent effect on production. The South African Mining and Engineering Journal of January 17, 1942, stated that the mining companies in Northern Rhodesia have expanded their operations considerably so that, in spite of the pegging of the price of their product, earnings have increased substantially. It said, however, that the financial return to those who made this expansion possible has descended sharply.

6 Barbour, Percy E., The War-Copper Situation: Am. Metal Market, September 23, 1941, p. 3.

The principal mines were, as usual, the Roan Antelope, Rhokana, and Mufulira. The proposed expansion at Nchanga, mentioned in the Copper chapter of Minerals Yearbook, 1940, Review of 1939, has been delayed because of the war, but the company reported a satisfactory increase in the production of concentrates in its pilot plant. According to the December issue of Engineering and Mining Journal, unofficial reports from Africa state that the Northern Rhodesia copper mines are delivering their copper in shapes that save time and labor for munitions manufacturers—evidently no longer merely in ingots, cakes, and bars.

The occupation of Madagascar by the British rather than by the Axis Powers in the first half of 1942 withdrew one of the threats to shipments of Northern Rhodesia and Belgian Congo copper from African ports.

Peru.—Peru ranks second to Chile in copper production in South America, and these two countries are the only important sources on that continent at present. Production in Peru usually amounts to somewhat more than 10 percent of the total for Chile and between 1 and 2 percent of that for the world. Unlike Chile, Peru broke no records in the production of copper in 1941 and its output, therefore, fell below the usual relationship. The Cerro de Pasco Copper Corporation, largest producer in the country, is credited with an output of 28,162 metric tons in 1941 compared with 33,538 tons in 1940 and 45,353 tons in 1929. This corporation has increased its output of lead sharply in recent years and is planning larger-scale production of zinc, Other copper producers in the country include the Northern Peru Mining Co., Sociedad Minera Puquio Cocha, Cie de Mines de Huaron, Compania Minera Rescate, and Sindicato Minero Rio Palanga.

Exports of copper contained in bars, concentrates, and ores totaled 36,417 metric tons in 1941 compared with 37,686 tons in 1940.

Philippine Islands.—Japan had been receiving the major part of the copper produced in the Philippine Islands, but in the latter part of 1941 exports to Japan were virtually embargoed. As a consequence the Hixbar Gold Mining Co., second-largest copper producer, was reported to have been forced to suspend mining operations; the mine has no concentrating plant, and Japan had been the only market for the grade of ore produced. A report prepared by the American consul in April 1941 stated that production in all of 1941 probably would amount to 9,900 metric tons, or between 5 and 10 percent above that in 1940. The shut-down at Hixbar may have prevented fulfillment of this estimate. At the end of 1941, Lepanto Consolidated was reported to be the only active copper producer in the Philippines.

Following successful invasion of the Islands by the Japanese in the early part of 1942 Japan can requisition, for a time at least, the entire output of the Philippines and can dictate the reopening of idle properties if desired.

Sweden.—Swedish authorities have prepared to improve their trade balance as regards copper. The annual production is reported to be 12,500 metric tons, and an increase of some 3,000 tons is anticipated as a result of an agreement between the Government and the Boliden Mining Co.—largest producer—regarding exploitation of certain Government-owned deposits in the Province of Västerbotten.

Recent reports originating in Sweden credit annual consumption in that country with 40,000 to 45,000 tons. On April 1, 1941, the Swedish Government expropriated all stocks of copper and decreed that copper and its alloys were to be sold under license only. Substitution of other metals for copper and brass was reported to be in progress in Sweden.

Union of South Africa.—Production of copper in the Union of South Africa has increased in recent years; data for 1941 are not available, but mine output totaled 13,350 metric tons in 1940 compared with 10,998 tons in 1939. The principal producer is the Messina mine, Northern Transvaal, and operations at that property were recently described.[7] Resumption of copper mining in Namaqualand by the O'okiep Copper Co., Ltd., was mentioned in the Copper chapter of Minerals Yearbook, Review of 1940.

Figures covering imports of blister and converter copper into the United States during the first 9 months of 1941 show that 6,021 metric tons were received from British South Africa. During the same period, 499 metric tons of copper in concentrates and small quantities of regulus and scrap were received. Data covering receipts of material in all of 1941 cannot be published.

LEAD [1]

By T. H. MILLER AND A. L. RANSOME

SUMMARY OUTLINE

GENERAL SUMMARY

The lead industry in 1941 was called upon to fill a growing and unprecedented demand. Lead was not only used as an essential war metal in direct military applications specified under the national defense program but as a substitute to help relieve the shortage of other nonferrous metals. As the result of this pressure, the industry showed moderate gains over 1940; but these advances were inadequate, despite the continued flow of metal into the United States from foreign sources, and by October lead was placed under Government control.

The output of refined primary lead from domestic and foreign ores was 7 percent above that in 1940 and the largest recorded since 1930. Production from domestic ores increased 9 percent, but that from foreign ores remained virtually unchanged from the high level established in 1940. The estimated industrial use of lead (primary, secondary, and antimonial) rose 34 percent and was 8 percent above the record established in 1929. As production failed to pace demand, year-end stocks at domestic refineries declined for the seventh consecutive year. This condition was balanced somewhat by a corresponding rise in consumers' inventories, which indicates that apparent consumption was greater than the amount actually used. Prices for lead at New York advanced from 5.50 cents a pound in January to 5.85 cents in April, at which point the quotation was stabilized for the rest of the year; the average price for the year increased from 5.18 cents in 1940 to 5.79 cents in 1941.

[1] This report deals primarily with the smelting, refining, and consuming phases of the industry. For full details of mining operations, see separate reports issued for the various States.

Salient statistics of the lead industry in the United States, 1925–29 (average) and 1937–41, in short tons

	1925–29 (average)	1937	1938	1939	1940	1941
Production of refined primary lead:						
From domestic ores and base bullion	660,525	443,142	331,964	420,967	433,065	470,517
From foreign ores and base bullion	123,104	24,175	51,705	63,068	100,114	100,450
	783,629	467,317	383,669	484,035	533,179	570,967
Recovery of secondary lead	280,000	275,100	224,900	241,500	260,346	397,416
Imports:[1]						
Lead in pigs, bars, and old	4,592	4,903	3,235	7,139	151,568	[2] 179,179
Lead in base bullion	95,747	1,800	15,296	48,902	19,624	[2] 23,631
Lead in ores and matte	40,096	34,103	45,370	30,842	111,300	[2] 58,082
Exports of refined pig lead	98,048	20,091	45,866	74,392	[3] 49,079	[2] 13,494
Lead remaining in bonded warehouse at end of period	136,969	60,131	87,811	79,215	211,876	[4] 153,289
Refined primary lead available for consumption	690,916	449,464	339,708	415,031	633,989	([5])
Estimated consumption of primary and secondary lead	900,250	678,700	546,000	667,000	782,000	1,050,000
Prices:						
New York:						
Average for year ..cents per pound	7.47	6.01	4.74	5.05	5.18	5.79
Quotation at end of year ..do	6.25	4.75	4.85	5.50	5.50	5.85
London average ..do	5.87	5.15	3.33	[6] 3.09	([7])	([7])
Mine production of recoverable lead	664,230	464,892	369,726	413,979	457,392	461,426
World smelter production of lead	1,850,000	1,851,000	1,878,000	1,919,000	([8])	([8])

[1] Data include lead imported for immediate consumption plus material entering the country under bond.
[2] Figures cover January to September, inclusive.
[3] Includes 25,324 tons of foreign refined lead re-exported, according to American Bureau of Metal Statistics; official figures not available.
[4] September 30.
[5] Figures not available for publication.
[6] Average for 8 months, London Metal Exchange dealings suspended for duration of war.
[7] Official maximum price fixed by British Ministry of Supply at £25 per long ton.
[8] Data not available.

Record quantities of lead continued to be received from abroad, largely in the form of refined metal principally from Mexico, but also in greatly increased tonnages from Canada, Australia, and Peru. Government stock piles of foreign lead purchased through the Metals Reserve Company were drawn on to bridge the gap between production and shipments; as a result, the large quantity of lead that had accumulated in bonded warehouses by the end of 1940 was notably depleted during the first 9 months of 1941.

Figure 1 shows trends in the domestic lead industry since 1900.

National defense activity.—All defense requirements necessitating the consumption of lead were met in 1941, including direct use in ammunition and in important indirect secondary military uses, such as batteries, paints, tetraethyl lead, and chemicals. One of the largest jobs for lead was in substitution for other metals, including aluminum, copper, zinc, and tin which were more important for war purposes and a great deal less abundant. Very little concern was felt as to lead supplies during the first part of 1941, and only nominal surveillance over the lead industry by the Production Division of the Office of Production Management was necessary. Following a previously issued warning, Leon Henderson, Commissioner of Price Stabilization of the Advisory Commission to the Council of National Defense, on April 5, 1941, requested that there be no further increase in the price of lead. This announcement, with its accompanying threat of ceiling prices, halted the upward trend, and no further change occurred during 1941.

Following the rapid expansion of lead consumption in early 1941, it was soon apparent that a shortage threatened, and, to conserve

supplies and prevent lead from getting unto unfriendly hands, the metal was placed under export control as of March 24, 1941. This order included lead in ore, matte, pigs, bars, and manufactures and on May 6 was extended to include lead pigments.

On May 1, 1941, General Metals Order 1, designed to restrict inventory accumulation of lead and various other metals not under priority control, was issued by the Office of Production Management. It remained in effect until October 4, when all supplies of lead, including domestic and imported, were placed under full priority control. The new control, provided for in Order M-38, set up a system of allocation that previously had been restricted to releases of foreign lead purchased and held by the Metals Reserve Company. An

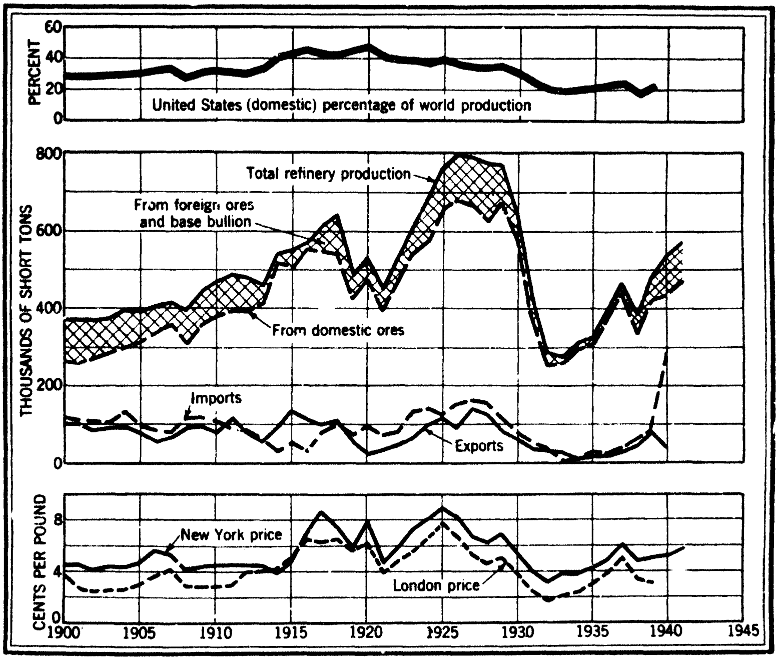

FIGURE 1.—Trends in the lead industry in the United States, 1900–1941. Imports include lead in ore, base bullion, pig lead, and scrap; exports include pigs, bars, and scrap lead exported in manufactures with benefit of draw-back.

emergency pool was set up to take care of special needs, and on October 23 the Division of Priorities of the Office of Production Management ordered refiners of lead to set aside 15 percent of their November production for allocation from this pool. The same percentage was ordered set aside for December and for each successive month of 1942 up to the time this review was written (June 25).

In an effort to ease the supply situation, an appeal was sent to all lead producers and miners by the Office of Production Management early in November, asking them to increase production. On January 13 the Office of Production Management, jointly with the Office of Price Administration, announced a two-point program to meet the urgent additional demands for copper, lead, and zinc that followed active entry into the war. With regard to lead, the program involved an increase in the price at New York to a ceiling of 6.50 cents a pound

and a payment, through the Metals Reserve Company, of a premium price of 9.25 cents for lead produced in excess of quotas based upon 1941 output. The premium-price plan was made effective as of February 1, 1942, for 2½ years.

DOMESTIC PRODUCTION

Pig lead is produced at primary plants that treat mainly ore and at secondary plants that treat scrap exclusively. Both types of plants may produce refined lead or antimonial lead. Because of the large quantity of battery scrap treated at secondary smelters, their output comprises chiefly antimonial-lead alloys. Figures for production of refined lead at secondary plants are shown in the section on Secondary Lead.

The following table shows production of refined lead and antimonial lead at primary refineries from 1937 through 1941.

Refined lead and antimonial lead produced at primary refineries in the United States, 1937–41, in short tons

Year	Refined lead				Antimonial lead
	From domestic ores and base bullion	From foreign ores and base bullion	From scrap	Total	
1937	443,142	24,175	29,986	497,303	27,524
1938	331,964	51,705	24,800	408,469	24,123
1939	420,967	63,068	29,011	513,046	21,995
1940	433,065	100,114	16,588	549,767	29,762
1941	470,517	100,450	13,454	584,421	40,237

PRIMARY LEAD

Refinery production.—Production of refined primary lead increased 7 percent in 1941 but was only 73 percent of the 1925–29 average (783,629 tons). Output from domestic ores and base bullion gained nearly 9 percent; production from foreign ores and base bullion remained virtually unchanged, with an increase of less than 1 percent from the high level attained in 1940, and was considerably less than the average (123,104 tons) for the period 1925–29.

Refined primary lead produced in the United States, 1937–41, by classes and sources

Year	Production (short tons) by—						Total production [1]		
	Class			Source			Short tons	Value	
	Desilverized lead [1] [2]	Soft lead [3]: Desilverized	Soft lead [3]: Undesilverized	From domestic ores and base bullion	From foreign ores	From foreign base bullion		Average sales price per pound	Total calculated value
1937	272,051	55,317	139,949	443,142	23,393	782	467,317	$0.059	$55,143,000
1938	243,891	31,986	107,792	331,964	32,862	18,843	383,669	.046	35,298,000
1939	280,356	65,349	138,330	420,967	24,652	38,416	484,035	.047	45,499,000
1940	336,456	43,400	153,323	433,065	83,563	16,551	533,179	.050	53,318,000
1941	366,385	39,872	164,710	470,517	74,166	26,284	570,967	.057	65,090,000

[1] Lead content of antimonial lead excluded.
[2] Desilverized soft lead excluded.
[3] Includes lead derived from Missouri ores and other nonargentiferous ores.

Sources of primary lead.—Of the total refined primary lead produced in 1941, 82 percent was derived from domestic ores and base bullion and 18 percent from foreign. Production from foreign ores decreased 11 percent from the all-time record established in 1940, but lead refined from foreign bullion advanced 59 percent. Details of the sources of lead from domestic ores are given in the section on Mine Production.

Refined primary lead produced in the United States, 1936–41, by sources, in short tons

Source	1936	1937	1938	1939	1940	1941
Domestic ore and base bullion	387,698	443,142	331,964	420,967	433,065	470,517
Foreign ore:						
Australia	172	3,088	7,320	7,580	14,856	19,561
Canada	2,277	5,343	3,562	4,763	9,009	5,708
Europe	1,133	388	14	188	3,650	123
Mexico	1,486	3,836	9,745	227	1,303	390
South America	3,883	8,497	9,887	8,869	34,744	27,173
Other foreign	2,450	2,241	2,334	3,025	20,001	21,211
	11,401	23,393	32,862	24,652	83,563	74,166
Foreign base bullion:						
Mexico	57	782	18,268	37,463	16,161	25,358
South America				9		47
Other foreign			575	944	390	879
	57	782	18,843	38,416	16,551	26,284
Total foreign	11,458	24,175	51,705	63,068	100,114	100,450
Grand total	399,156	467,317	383,669	484,035	533,179	570,967

Antimonial lead.—Antimonial or hard lead is an important byproduct of the refining of base bullion, but the quantity derived from this source is only a small part of the country's yearly production. The major part is obtained from the smelting of antimonial-lead scrap, and some is produced by mixing metallic antimony with refined soft lead.

Several lead-smelting plants handle scrap materials exclusively. Production data from such plants are summarized in the following section and discussed in detail in the chapter on Secondary Metals—Nonferrous. A large quantity of hard-lead scrap also is treated at primary smelters and refineries; the production of antimonial lead at such plants is shown in the following table.

Antimonial lead produced at primary lead refineries in the United States, 1937–41

Year	Production (short tons)	Antimony content		Lead content by difference (short tons)			
		Short tons	Percent	From domestic ore	From foreign ore	From scrap	Total
1937	27,524	2,579	9.4	7,833	1,721	15,391	24,945
1938	24,123	2,809	11.6	6,759	3,385	11,170	21,314
1939	21,995	2,031	9.2	4,117	3,189	12,658	19,964

1941	40,237	3,510	8.7	14,852	8,013	13,862	36,727

SECONDARY LEAD

As previously stated, some scrap lead is treated at primary plants, but the greater part is refined at a large number of plants that operate exclusively on secondary materials. Secondary lead is recovered in the form of refined lead, antimonial lead, other alloys, and chemicals. Recovery at primary and other plants in 1940 and 1941 is shown in the following table. Secondary lead recovered in 1941 totaled 53 percent more than in 1940 and was equivalent to 84 percent of the domestic refined primary lead output. Further details appear in the chapter on Secondary Metals—Nonferrous.

Secondary lead recovered in the United States, 1940–41, in short tons

	1940	1941
As refined metal:		
At primary plants	16,588	13,454
At other plants	42,992	61,810
	59,580	75,264
In antimonial lead:		
At primary plants	16,431	13,862
At other plants	110,256	192,660
	126,687	206,522
In other alloys [1]	74,079	115,630
Grand total:		
Short tons	260,346	397,416
Value	$26,034,600	$45,305,400

[1] Includes some lead in chemical compounds.

LEAD PIGMENTS

Lead pigments manufactured in 1941 contained 273,315 tons of lead—a 28-percent increase above 1940. Of the 248,674 tons of lead in pigments derived from refined pig lead, litharge contained 45 percent, white lead 35 percent, red lead 19 percent, and sublimed lead, leaded zinc oxide, and orange mineral 1 percent. Leaded zinc oxide and sublimed lead are the principal pigments of which the lead content is derived from ores. Details of production and consumption of lead pigments are given in the chapter on Lead and Zinc Pigments and Zinc Salts.

Lead in pigments produced in the United States, 1937–41, by sources, in short tons [1]

Year	Lead in pigments from—				Year	Lead in pigments from—			
	Ore		Metal	Total		Ore		Metal	Total
	Domestic	Foreign				Domestic	Foreign		
1937	17,363		204,961	[2] 222,451	1940	16,869		196,235	213,104

1939	15,171		200,390	215,561					

[1] Includes also lead recovered in leaded zinc oxide.
[2] Includes 127 tons from scrap.
[3] Includes 400 tons from scrap.

MINE PRODUCTION

Mine production of lead showed an advance in each group of States—Western, Central, and Eastern—but the over-all gain during 1941 was only about 1 percent. The comparatively minor increases amounted to 1,577 tons in the Western States and Alaska, 1,775 tons in the Central States, and 682 tons in the Eastern States. Lead production from Southeastern Missouri was 164,342 tons, a decline of 5,551 tons, whereas output from the Tri-State region amounted to 41,080 tons, an advance of 5,769 tons. Gains in Oklahoma and Kansas more than offset a loss from Southwestern Missouri in 1941. Idaho continued to be the leading producer in the Western States group and was followed again by Utah and Montana; output from Idaho was only a few tons more than in 1940, and production from both the other States was less. The decrease in Utah's total is explained chiefly by decreases in output from the United States & Lark property and the National Tunnel & Mines Co. property (operations ceased about September 1941), both in the Bingham district. The principal factors causing the decline in Montana were the production drop from the Jack Waite mine and the closing, in April 1941, of the Comet-Gray Eagle group. Arizona produced 15,638 tons of recoverable lead in 1941, the greatest output in the history of the State. In Colorado the production of lead was 12,574 tons and in Nevada 9,623 tons; both totals were above the 1940 figures, as was also true for New Mexico and Washington. Additional details of production by mines, districts, and States can be found in the State chapters.

Mine production of recoverable lead in the United States, 1925–29 (average) and 1937–41, by States, in short tons

[1] Corrected figure.
[2] Bureau of Mines not at liberty to publish figures.
[3] Total for Virginia but almost entirely from Austinville district.

STOCKS

Producers' stocks.—Lead stocks, as reported by the American Bureau of Metal Statistics, are shown in the following table. Stocks of refined and antimonial lead include metal held by all primary refiners and by most refiners of secondary material who produce common lead. Foreign lead refined in the United States and entered for domestic consumption is included.

Lead stocks at end of year at smelters and refineries in the United States, 1937–41, in short tons

	1937	1938	1939	1940	1941
Refined pig lead	119, 837	102, 489	52, 783	32, 458	15, 973
Antimonial lead	9, 294	13, 413	5, 994	8, 468	4, 212
	129, 131	115, 902	58, 777	40, 926	20, 185
Lead in base bullion—					
At smelters and refineries	10, 959	18, 693	10, 337	9, 166	8, 594
In transit to refineries	2, 219	2, 339	3, 521	3, 457	2, 215
In process at refineries	14, 413	16, 690	15, 958	18, 141	17, 709
	27, 591	37, 722	29, 816	30, 764	28, 518
Lead in ore and matte and in process at smelters	52, 081	56, 332	59, 486	71, 722	51, 446
	208, 803	209, 956	148, 079	143, 412	100, 149

During 1941 the excess of shipments over production resulted in generally decreasing inventories for the year. Stocks of refined and antimonial lead at refineries, which totaled approximately 40,900 tons at the end of 1940, rose to 47,200 tons by the end of January—the peak for 1941—but this initial gain was followed by a steady drop to a low of 10,700 tons by the end of October. During the remaining 2 months, increased production more than balanced a parallel gain in shipments, but refinery inventories (which rose to about 20,200 tons at the end of 1941) were only 49 percent of those on hand at the end of 1940. Stocks of lead in ore and matte and in process at smelters, in base bullion at smelters and refineries, and in transit to and in process at refineries were 22 percent lower at the end than at the beginning of 1941.

Consumers' stocks.—In the Bureau of Mines survey of the consumption of refined soft lead in 1941 (discussed in this chapter under the heading Domestic Consumption), consumers were asked to give their stocks of the three commercial grades of refined soft lead at the beginning and end of 1941. The results obtained give for the first time an inventory picture of the consumer phase of the lead industry. The totals shown in the following table indicate a marked increase in stocks, amounting to 33 percent. Consumers' stocks gained 25,865 tons during the year and more than offset the decrease of 16,485 tons in producers' inventories of refined lead, indicating conclusively that consumption of lead was less than producers' shipments.

Consumers' stocks of refined soft lead at beginning and end of 1941, by grades, in short tons [1]

	Domestic			Foreign (all grades)	Total
	Corroding	Chemical	Common		
Dec. 31, 1940	24,880	12,436	36,977	4,177	78,470
Dec. 31, 1941	36,351	17,209	36,251	14,524	104,335

[1] Based upon survey of approximately 475 companies.

DOMESTIC CONSUMPTION

New supply.—A complete picture of the increased supply of refined primary lead available for consumption in 1941 cannot be published, owing to the confidential nature of foreign trade information since September 1941. In the following table the apparent trend of supply is shown for the 4 years, 1937–40, but no attempt has been made to total the incomplete 1941 statistics. In 1941, imports that affect the total supply and exports that largely determine withdrawals are listed only for January to September, inclusive. The figures do not consider variation in producers' stocks, and as these have changed considerably during the past 5 years the quantities stated do not show the true trend in actual consumption of new lead.

Refined primary pig lead available for consumption in the United States, 1937–41, in short tons

	1937	1938	1939	1940	1941
Supply:					
Imports	2, 238	1, 905	5, 388	149, 889	[1] 179, 086

[1] Figures cover January to September, inclusive
[2] Figures not available for publication
[3] Includes small quantity of "sheets and pipes"; figures not separable.
[4] Includes 25,324 tons of foreign refined lead re-exported, according to American Bureau of Metal Statistics; official figures not available.

Consumption.—Consumption of lead in the United States during 1941 broke all records. The metal not only served as a war material in military applications and other defense uses but was called upon to help relieve the shortage of other metals, including aluminum, copper, zinc, and tin. Owing to the return of large quantities of secondary lead in discarded and obsolete articles and from the lead-consuming industries, the total consumption of pig lead greatly exceeds the supply of new lead available. The following table gives the American Bureau of Metal Statistics estimate of the total consumption of lead by industries, 1937–41.

Lead consumed in the United States, 1937–41, in short tons [1]

Purpose	1937	1938	1939	1940	1941
White lead	86, 000	71, 000	75, 000	65, 500	85, 000
Red lead and litharge	57, 000	43, 000	57, 200	59, 400	89, 100
Storage batteries	192, 000	167, 000	198, 000	220, 200	245, 000

Castings	6, 000	6, 000	7, 500	9, 000	14, 000
Other uses	54, 100	51, 500	63, 100	85, 000	99, 700
	678, 700	546, 000	667, 000	782, 000	1, 050, 000

[1] American Bureau of Metal Statistics. These estimates are for total consumption of lead, irrespective of whether its origin is primary or secondary. Antimonial lead is included.

The quantity of lead consumed by industry in 1941, as estimated by the American Bureau of Metal Statistics, was 34 percent above that in 1940 and 8 percent greater than the previous high level established in 1929. The principal use of lead is in the manufacture of storage batteries, and in recent years requirements of lead for this purpose have averaged approximately 30 percent of the total. Although the lead thus used in 1941 reached a new record high, the amount was only 23 percent of the total lead consumed, as all uses increased over 1940. This high figure reflects the efforts of the automobile industry to produce a record number of vehicles before conversion of plant facilities to war production plus expanded production

of batteries for strictly military and naval use. Under normal conditions, lead withdrawn for use in storage batteries noticeably curtails the need for newly mined metal, as it rapidly returns to the trade in the form of scrap and there competes with the primary market. The use of lead for cable covering ranked again second but increased 61 percent. Although the white-lead industry dropped to fifth place, following increased consumption of lead for building and for red lead and litharge, the amount of lead used was 30 percent more than in 1940.

The increases in use of white lead, and also red lead (which advanced 50 percent), were due principally to the shortage of other pigments derived from aluminum, zinc, and titanium. Compared with the former record year 1929, lead consumption for the six major uses in 1941 was as follows: Use in storage batteries was greater by 17 percent, red lead and litharge 197 percent, and ammunition 74 percent; cable covering was 79 percent of the 1929 figure, white lead 71 percent, and building 99 percent. Of all the uses listed, six were higher in 1941 than in 1929 as compared with four in 1940.

In January 1942 the Bureau of Mines started a consumer survey of the use of refined soft lead during 1941. The results of this survey of approximately 475 companies are shown in the following table. Judging from available data as regards supply, shipments, and producers' stocks, the receipts of 838,835 tons of refined soft lead by those consumers canvassed indicate that the coverage was substantially complete. However, the total does not represent the entire consumption, as antimonial lead, unrefined scrap lead, and lead in alloys are not included. As this survey is the first attempt to show the actual picture of the consumer side of the industry, no comparative analysis can be made with 1940 or earlier years.

Consumption of refined soft lead in the United States in 1941, by grades and uses, in short tons [1]

By grades:		By uses—Continued.	
Domestic:		Collapsible tubes	3,726
Corroding	289,970	Foil	51,516
Chemical	150,237	Pipes, traps, and bends	32,946
Common	257,114	Sheet lead	35,480
Foreign: All grades	115,649	Solder	56,622
		Storage batteries	53,082
Total consumed	812,970	Terneplate	3,069
		Type metals	2,975
By uses:		White lead	83,230
Ammunition	33,011	Red lead and litharge	143,496
Bearing metals	10,318	Chemicals and insecticides	8,861
Cable covering	137,659	Other uses [2]	112,840
Calking lead	35,876		
Casting metals	9,263	Total consumed	812,970

[1] Based upon survey of approximately 475 companies; subject to revision.
[2] Includes consumption of lead in manufacture of tetraethyl lead used in tempering gasoline.

PRICES

The two major markets for lead in the United States are New York and St. Louis; much of the lead produced in this country is sold at prices based upon quotations in these markets. As the New York quotations are influenced to some extent by the lower prices that, in normal times, usually prevail on the London market, the New York price seldom exceeds the St. Louis price by as much as the freight difference (usually 0.35 cent a pound).

In 1941 the average prices for lead did not fluctuate, as in 1940, but followed the trend of the other common nonferrous metals and rose during the first quarter to a point of stabilization that was maintained for the rest of the year. The price for pig lead at New York, outside market, at the beginning of 1941 was 5.50 cents a pound. During subsequent weeks of heavy purchases the price advanced to 5.65 cents on February 10. Consumption continued to increase—at least in part attributable to additions to consumer inventory—and the quotation again jumped, rising to 5.75 cents on March 3. The increased use of lead as a substitute material for scarcer commodities added to the ever-growing demand, and the price advanced once more. This last step-up raised the quotation to 5.85 cents on March 26. What appeared to be forward buying on the part of consumers resulted in a continuation of demand above actual requirements. On April 5 the Office of Price Administration declared the possibility of a price ceiling and requested leading producers to refrain from further increases in price. This unofficial request was followed, and the price remained at 5.85 cents for the remainder of 1941. The average price for 1941 was 5.79 cents compared with 5.18 cents in 1940 and 5.05 cents in 1939.

Information regarding London Metal Exchange dealings, which were suspended at the outbreak of the war, continued to be unavailable during 1941.

In September 1939 the British Ministry of Supply announced the establishment of the maximum price of Empire lead at £17 per long ton ex ship and of foreign lead at £16 12s. 6d. ex ship. In December 1939 the Nonferrous Metal Control for the United Kingdom raised the price of Empire and foreign lead to £25 per long ton, duty paid, delivered. There was no reported change from this figure during 1941.

Average monthly and yearly quoted prices of lead at St. Louis, New York, and London, 1939–41, in cents per pound [1]

Month	1939			1940			1941		
	St. Louis	New York	London	St. Louis	New York	London	St. Louis	New York	London

[1] St. Louis: Metal Statistics, 1942, p. 473. Average daily quotations of soft Missouri lead, f. o. b. St. Louis (open market), as reported daily in American Metal Market.
New York: American Metal Market, daily issues. Pig lead, New York (outside market), prompt shipment from West.
London: Metal Statistics, 1942, p. 478. Average price of foreign lead. Price per long ton, as published in Metal Statistics, converted to cents per pound at average exchange rate reported by Federal Reserve Board.

[2] London Metal Exchange dealings suspended for duration of war. Official maximum price fixed by British Ministry of Supply at £25 in December 1939.

[3] London quotation in pounds sterling per long ton for first 8 months of 1939 was £14.7083.

[4] Average for 8 months; comparable average for New York was 4.83 cents.

FOREIGN TRADE [2]

As foreign trade statistics for 1941 can be given for only the 9-month period from January to September, no direct comparison can be made with 1940 totals. The figures do show that total lead imported during the period more than maintained the high level reached in 1940.

Imports.—Lead imported in the 9-month period totaled 260,892 short tons. Of this amount, pigs, bars, and old comprised 69 percent, lead in ore and matte 22 percent, and lead in base bullion 9 percent; the comparative ratio for 1940 was 54, 39, and 7 percent, respectively. Imports of pigs, bars, and old during 1941 continued to gain, and the 9-month total was substantially above the high level of 1940. Mexico, for years the principal source of imports of unrefined lead, contributed 38 percent of the total tonnage during the 9 months, followed by Canada with 21 percent. In 1940 the ratio was 53 and 3 percent, respectively, which indicates a remarkable gain from the latter country that was almost entirely in the form of pigs, bars, and old. This same category included notable tonnages from Australia and Peru. Mexico remained the principal source.

Total lead imported into the United States, 1937–41, by forms in which imported, in short tons [1]

Year	Lead in ore and matte	Lead in base bullion	Pigs, bars, and old	Total lead content
1937	34, 103	1, 800	4, 903	40, 806
1938	45, 370	15, 296	3, 235	63, 901
1939	30, 842	48, 902	7, 139	86, 883
1940	111, 300	19, 624	151, 568	282, 492
1941 (Jan.-Sept.)	58, 082	23, 631	179, 179	260, 892

[1] Data include lead imported for immediate consumption plus material entering country under bond.

Total lead imported into the United States, in ore, base bullion, and refined, 1937–41, by countries, in short tons [1]

Year	Canada	Mexico	New-found-land	South America [2]	Europe	Other countries	Total
1937	5, 749	17, 068		13, 229	535	4, 225	40, 806
1938	3, 174	38, 467		13, 426	680	8, 154	63, 901

[1] Includes sheets and pipes; figures not separable.
[2] In addition, 25,324 tons of foreign lead were re-exported, according to American Bureau of Metal Statistics; official figures not available.
[3] Less than 1 ton.

WORLD ASPECTS OF LEAD INDUSTRY

A statistical picture of the lead situation throughout the world in 1941 is more difficult to draw than in 1940, owing to an even greater scarcity of production data.

Although official data are lacking, it is doubtful if world production and consumption gained much in 1941; indeed, the reverse may have been true.

Some ot the details by countries, insofar as data are available under existing conditions of wartime restrictions, are discussed in the following pages.

REVIEW BY COUNTRIES

Argentina.—The Compania Minera Aguilar S. A., subsidiary of the St. Joseph Lead Co., supplied nearly 98 percent of the Argentine output of lead in 1941. During the year, Argentina produced 32,317 metric tons of 74-percent lead concentrates; in 1940 the output of concentrates amounted to 40,097 tons. From January to September (inclusive) 1941, 4,615 metric tons of lead ore were imported, almost entirely from Bolivia, compared with 2,888 tons for the same period in 1940. Nearly all the primary lead produced in Argentina comes from the National Lead Co. smelter at Puerto Vilelas; although the 1941 total is not known, production probably exceeded the 1940 figure of 12,864 metric tons, which included 2,476 tons from foreign ore.

Australia.—Although figures relating to production in Australia are not available for 1941, increased nonferrous metal-mining activity would appear to indicate an advance in lead output. Mt. Isa Mines, Ltd., continued to produce lead bullion steadily throughout 1941. The average mill extraction for the year ended June 30 was 79.7 percent lead recovered. During the year mining and milling continued at the property of the Lake George Mining Corporation, New South Wales, but toward the end of 1941 the lessened labor supply resulted in reduced output in the mine. With increased scarcity of shipping plus other factors, lead concentrates equal to nearly 8 months production had accumulated by the end of the year.

In Tasmania the North Farrell mine at Tullah is now the only producer of silver-lead ore. Output from the mine is reported to be 80 to 100 tons of concentrates a month.

Bolivia.—Mine production of lead in Bolivia, derived principally from small mines in the La Quiaca region, amounted to 15,654 metric tons contained in 26,356 tons of ore and concentrates. Production of lead in 1940 was 11,662 tons (content in ore). All concentrates are exported, during past years almost entirely to Argentina. The Bolivian Government has given the United States the exclusive right to purchase lead output, but during 1941 exports were divided between the United States and Argentina. It is reported that the Bolivian Banco Minero allotted 504,000 bolivianos for the erection of a lead smelter.

Brazil.—Production of lead remains comparatively undeveloped in Brazil. The Furnas lead-silver mine in the Iporanga district, State of São Paulo, is the principal producer and has considerable reserves of ore. The new selective-flotation plant of 35-ton daily capacity at Palmital treats ore averaging about 7 percent lead, 17 percent zinc, and 7 ounces of silver per ton and produces a 55.6-

percent lead concentrate containing 50 ounces of silver per ton. Recovery is approximately 79 percent. Operating in conjunction with this plant is a new lead-silver smelter completed in July 1941—the first to be built in Brazil. Potential daily capacity, following pilot-plant operations, is 10 metric tons of refined lead and 25 kilograms of silver; the lead produced will be placed on the domestic market, and the silver will go to the mint. Power for the operations is obtained from a hydroelectric plant at Salto do Colabouco on the Palmital River near Apiai. Although a larger output from the district is expected, the mines do not produce enough at present to keep the smelter operating at full capacity.

Canada.—Although data on production of lead in Canada continued to be unavailable, it is understood that the Canadian metal industry more than maintained the high production rate attained in 1940. The Sullivan mine of the Consolidated Mining & Smelting Co., in British Columbia, reputedly produced 90 percent of the total Canadian lead output. Large quantities have been shipped to the United States through contract with the Metals Reserve Co., and reserve stocks are reportedly near exhaustion. Mining has been resumed at numerous smaller properties, including that of the Lake Geneva Mining Co., Ltd., northwest of Sudbury and at the old Calumet Island property near Ottawa.

Arrangements have reportedly been made by Reeves McDonald Mines, Ltd., to construct a zinc-lead smelter at its property in the West Kootenay district of British Columbia to be in operation late in 1942.

Mexico.—Mine production of lead in Mexico during 1941 amounted to 155,259 metric tons, a considerable decrease from the 196,250 tons produced in 1940. Exports of lead in all forms from January to September (inclusive) 1941 totaled 114,603 metric tons compared with 138,739 tons for the same period in 1940. Of this total, 90,116 tons (nearly 79 percent) were exported to the United States compared with 79 percent for the entire year 1940.

Mexico continued to have labor problems in 1941. The American Smelting & Refining Co. closed its Monterrey refinery in the State of Nuevo León, owing to a strike on April 28, and did not reopen it until June 16. The capacity of the refinery is 18,000 tons a month. There was also a strike at the Monterrey refinery of the American Metal Co., Ltd., from September 8 to October 20; it adversely affected Mexican output, and full production was not resumed for some time after its settlement.

Peru.—Mine production of lead in Peru in 1941 totaled 54,822 metric tons compared with 50,439 tons in 1940. Exports from Peru during 1941 included an estimated 8,000 tons of lead ore, 12,000 tons of concentrates, and 38,000 tons of pig lead, compared with 5,430, 19,086, and 23,241 tons, respectively, in 1940. Of the total lead shipped, the Cerro de Pasco Copper Corporation supplied about 85 percent. The corporation is installing a third lead furnace at the Oroya smelter—the only one in Peru—to keep the refinery operating at capacity. Output of refined lead will be increased to about 45,000 tons annually. Construction of the new 800-ton-per-day lead-zinc concentrator is progressing, but the plant is not scheduled for completion before late 1942 or in 1943.

Spain.—Little information has been available regarding the Spanish lead industry during and following the years of the Spanish Civil War, which was concluded in 1939. It is reported that mine production of lead in 1940 amounted to about 57,900 metric tons and that 42,400 tons of metal were produced. For 10 months of 1941, mine and metal production has been given as approximately 35,600 and 24,400 tons, respectively.

Sweden.—In an effort to alleviate the acute lead shortage, the Swedish Boliden Mining Co. is preparing to mine and concentrate lead ore. The concentrates will be shipped to the Rönnskär smelter at Skelleftead for treatment. The company has extensive holdings at Laisvall in northern Sweden.

ZINC[1]

By A. L. Ransome

SUMMARY OUTLINE

GENERAL SUMMARY

The zinc industry in 1941 again was characterized by its well-geared relationship with the national defense program. The spirit of cooperation between Government and the zinc industry resulted in a year of smooth-running but intense activity that broke all records in an endeavor to meet increased demands for the metal. The smelting industry increased its output 22 percent over 1940 to a new all-time record and at the same time managed to show a gain of 26 percent in stocks above the low point reached at the end of 1940. The augmented supply was inadequate, and consumers' stocks continued to decrease. Continued heavy demand for high-grade zinc resulted in a 29-percent gain in output above the exceptionally high total for 1940. In comparison, the lower grades of zinc advanced 16 percent. At the close of 1941, smelters were operating at usable capacity, which was 96 percent of the total available, with additional capacity under construction and planned in excess of new capacity added since 1940.

Although domestic mine output increased 13 percent to a point only 3 percent below the 1926 record, it could not meet the gain in consumption, and smelters continued to use foreign ore in even greater amounts than in 1940. Imports in the first 9 months of 1941 exceeded the previous record for 1940 (12 months) and sufficed to establish an all-time record for domestic output of zinc from foreign ores, as well as a marked increase in ore inventories at the smelters.

[1] This report deals primarily with the smelting branch of the industry. Full details of zinc mining are given in the various State reports. Some zinc ore is used directly in the manufacture of zinc pigments. See chapter on Lead and Zinc Pigments and Zinc Salts.)

Salient statistics of the zinc industry in the United States, 1925–29 (average), and 1937–41

[1] Figures not available for publication.
[2] Average for 8 months, London Metal Exchange dealings suspended in September
[3] Data not available

Only one change was made in the price of slab zinc after September 24, 1940. On October 9, 1941, the Office of Price Administration raised the official quotation for Prime Western zinc at St. Louis from 7.25 to 8.25 cents a pound in an effort to expand output from marginal producers. This was the highest price level reached in 15 years. The average quoted price for 1941 was 7.48 cents compared with 6.34 cents in 1940 and 5.12 cents in 1939.

Figure 1 shows trends in the domestic zinc industry since 1900.

National defense activity.—The rising tide of defense preparations during 1941, plus the initiation of Lend-Lease activities, was climaxed in December by the unprovoked Japanese attack upon Pearl Harbor. Thus the year closed with an abrupt change from a national policy of defense against aggression to active participation in the world conflict, with accompanying necessary alterations in the peacetime industrial pattern.

During 1940 the shortage of zinc became more acute, and by the end of the year producers had voluntarily initiated a system of allocating supplies of zinc to consumers. Imposition of Government priorities in deliveries was suggested as early as November, but no positive action was taken until March 1941. On January 30, 1941, a Priorities Committee for Nonferrous Metals was established in the Priorities Division of the Office of Production Management. Exports of zinc ores, slab zinc, and manufactures of zinc were added to the list of materials subject to export control on February 3. On February 20 the American Zinc Institute appointed a committee to coordinate

zinc supplies between producers and consumers. The tight situation continued, and informal action was taken by the Priorities Division to facilitate the flow of zinc into military uses, nondefense consumers being urged to cooperate voluntarily.

On March 7 the Office of Production Management announced the creation of a zinc pool effective for April, when an amount of zinc equal to 5 percent of the January output would be requisitioned from the April production to alleviate shortages in defense industries. The pool requirements increased throughout the remainder of 1941 and

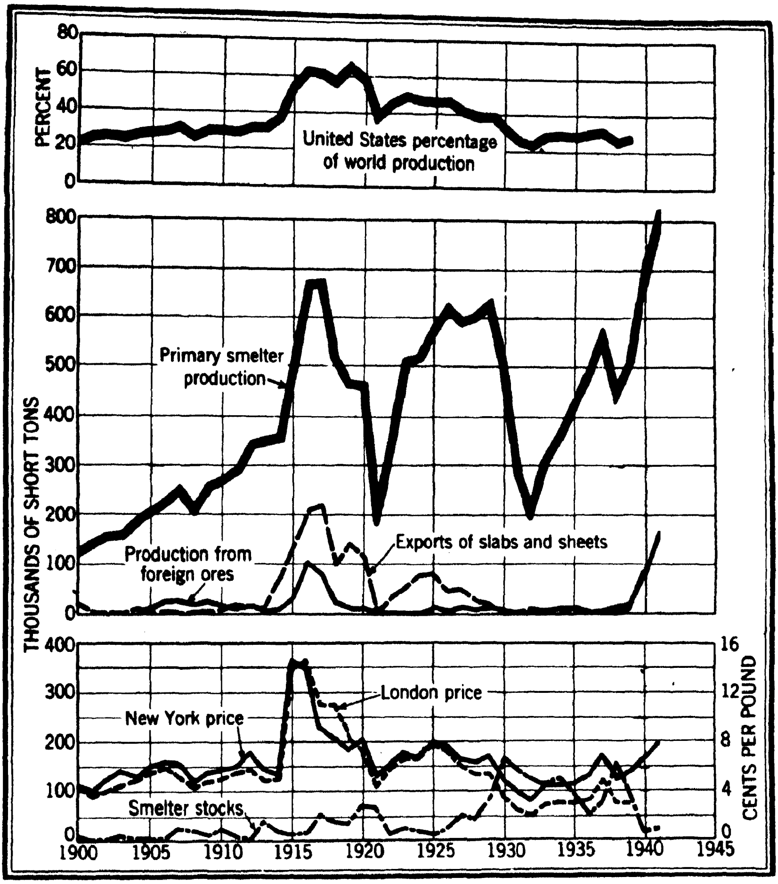

FIGURE 1.—Trends in the zinc industry in the United States, 1900–1941. Imports for consumption of slab and sheet zinc are not shown; before 1936 they seldom exceeded 500 tons annually, but in recent years they have increased, amounting to 37,439 tons in 1937, 7,456 tons in 1938, 31,138 tons in 1939, 10,164 tons in 1940, and 31,066 tons in 1941 (January–September, inclusive).

until May 1942, when amounts were set at 75 percent of high-grade and 50 percent of the lower grades based upon January production. The following table lists the zinc-pool percentage requirements by months, as ordered by the Office of Production Management during 1941 and by the War Production Board after creation of that agency on January 16, 1942, to absorb and take over the duties of the Office of Production Management.

Zinc-pool percentage requirements

From production in—		An amount equal to—
1941	April	5 percent of January 1941 total output.
	May	17 percent of March 1941 total output.
	June	22 percent of April 1941 total output.
	July	22 percent of May 1941 total output.
	August	27 percent of June 1941 total output.
	September	27 percent of July 1941 total output.
	October	27 percent of August 1941 total output.
	November	31 percent of August 1941 total output.
	December	29 percent of August 1941 total output.
1942	January	31 percent of October 1941 total output.
	February	40 percent of November 1941 total output.
	March	50 percent of December 1941 high-grade [1] output. 40 percent of December 1941 lower grade [2] output.
	April	60 percent of January 1942 high-grade [1] output. 40 percent of January 1942 lower grade [2] output.
	May	75 percent of January 1942 high-grade [1] output. 50 percent of January 1942 lower grade [2] output.

[1] Special High Grade and Regular High Grade
[2] Intermediate, Brass Special, Selected, and Prime Western

The Division of Industry Operations of the War Production Board announced on May 1 that zinc would be placed under full allocation on June 1. The same order stated that zinc produced from foreign ores in bond could be re-exported upon issuance of a license by the Office of Export Control of the Board of Economic Warfare.

Smelting capacity.—Under existing conditions of all-out production, zinc-smelting capacity is best measured by actual production data with estimated future production based upon added capacity of new facilities under construction and planned. Industry's estimate of 1941 production (announced in February 1941) from ores and secondary material (excluding production from graphite retorts) was 864,000 short tons. This figure came remarkably close to the actual comparable total of 863,263 tons as compiled by the Bureau of Mines. It has been estimated that total production of 881,523 tons of primary and secondary metal in the United States in 1941 will be increased to 956,000 tons[2] in 1942 by the use of additional capacity under construction, with the possibility of even further expansion for 1943. The results of the feverish activity in the zinc industry to adjust itself to war economy and enlarge production can best be judged by comparing present data with those for 1938, when the output was 478,000 tons.

Supply of zinc concentrates.—In 1941 the domestic mine production of zinc increased 13 percent over the 1940 total, owing in large part to the increase in price of zinc. Domestic supply of ore was supplemented by amounts of foreign concentrates large enough to produce the record 1941 output of metal plus necessary uses of ore in other industries, and still build up a considerable inventory of ore and concentrates by the end of 1941. The Office of Production Management, jointly with the Office of Price Administration, on January 13, 1942, announced the details of a premium-price plan, whereby producers of zinc (copper and lead are also included in the plan) would receive, through the Metals Reserve Co., 11 cents a pound for zinc produced in excess of quotas based upon 1941 output, effective as of February 1, 1942, for 2½ years. Although the result undoubtedly will be an increased domestic production, the percentage gain is

[2] Young, Howard I., Slab Zinc Review: Am. Zinc Inst. Ann. Convention, April 29, 1941; mim. by that agency.

conjectural. The expected increase in the rate of production has been estimated (according to the joint O. P. M.–O. P. A. announcement of January 13) at 30 percent by the end of 1942, as compared with the 1941 year-end rate. Even considering such a possible increase this country must still look to imports of foreign concentrates to continue at about the same rate as in 1941. This import rate must, if possible, be maintained by increasing imports from sources that involve rail movements rather than ships, in view of the hazards that today accompany ocean transport.

DOMESTIC PRODUCTION

Production of primary and redistilled secondary slab zinc.—The production of 822,020 short tons of primary slab zinc from domestic and foreign ores in 1941 was the highest ever recorded and exceeded the previous record of 1940 by 22 percent; the total was 23 percent higher than that for the peak year of 1917 and 37 percent more than the average annual output in the 5 years 1925–29. Both domestic and foreign ores contributed to the increase, as production from the former source advanced 11 percent and that from the latter 99 percent. The output from domestic ores was the largest on record, and the quantity produced from foreign ores was 63 percent greater than the previous high of 104,005 tons in 1916.

The production of redistilled secondary slab zinc increased 22 percent. To prevent inadvertent duplication, figures for the output of remelted secondary slab zinc are not included with those for redistilled metal. In 1941, 10,389 tons were recovered by remelting purchased scrap. Zinc rolling mills and other consumers recover considerably more than this from their own plant scrap, but such metal normally does not enter the market and is not measured statistically.

Primary and redistilled secondary slab zinc produced in the United States, 1937–41, in short tons

Year	Primary			Redistilled secondary	Total (excludes remelted)
	Domestic	Foreign [1]	Total		
1937	551,165	5,739	556,904	51,554	608,458
1938	436,007	10,334	446,341	31,613	477,954
1939	491,058	16,178	507,236	50,428	557,664
1940	589,988	85,287	675,275	48,917	724,192
1941	652,599	169,421	822,020	59,503	881,523

[1] Most of the foreign ores smelted in the United States in 1937-38 originated in Peru; in 1939, in Mexico, Peru, and Argentina; and in 1940-41, principally in Mexico, Canada, Newfoundland, and Peru

Distilled and electrolytic zinc.—Of the primary zinc produced in 1941, 73 percent was distilled and 27 percent electrolytic compared with 72 and 28 percent, respectively, in 1940.

Because of the significant part of zinc in the manufacture of items both for military and civilian uses, producers were requested to report their output of each grade in 1941. In 1940 Special High Grade was separately reported for the first time, and the 1941 statistics show a continued exceptional demand for this grade that was exceeded only by Prime Western. All grades that were directly comparable with

1940 figures showed increases. Special High Grade gained 4 percent, Regular High Grade 79 percent, Intermediate 15 percent, and Prime Western 22 percent. The combined total of Brass Special and Selected was slightly less than the comparable figure for 1940; these two grades, not segregated in preceding years, amounted to only 8 and less than 1 percent, respectively, of the total zinc production in 1941.

Distilled and electrolytic zinc, primary and secondary, produced in the United States, 1937–41, in short tons

APPORTIONED ACCORDING TO METHOD OF REDUCTION

Year	Electrolytic primary	Distilled primary	Redistilled secondary [1]		Total
			At primary smelters	At secondary smelters	
1937	117,511	439,393	24,131	27,423	608,458
1938	93,272	353,069	14,003	17,610	477,954
1939	127,056	380,180	23,471	26,957	557,664
1940	187,040	488,235	20,003	28,914	724,192
1941	224,313	597,707	27,904	31,599	881,523

APPORTIONED ACCORDING TO GRADE

Year	Grade A		Grade B (Intermediate)	Grades C and D		Grade E (Prime Western)	Total
	Special High Grade (99.99%Zn)	Ordinary		Brass Special	Selected		
1937	196,052		67,132	72,993		272,281	608,458

1939	162,345		66,591	86,274		242,454	557,664
1940	195,119	98,940	65,321	80,681		284,131	724,192
1941	203,030	177,451	74,797	73,968	5,152	347,125	881,523

[1] For total production of secondary zinc see chapter on Secondary Metals—Nonferrous.

Production of primary slab zinc by States.—Pennsylvania continued to be the leading producer of primary slab zinc in the United States, a distinction held without interruption since 1934. Montana and Illinois ranked next in order of importance, closely followed by Oklahoma. The positions of Arkansas and Idaho were reversed from 1940, and Arkansas again took the lead over Idaho. All producing States continued to show gains; the increases were particularly marked in Pennsylvania, Illinois, and the West Virginia-Texas group, where they were 27, 20, and 42 percent, respectively. Montana and Idaho, as usual, produced electrolytic zinc only. Whereas all other States produced distilled zinc only in 1940, Illinois produced electrolytic zinc as well as distilled metal in 1941.

Primary slab zinc produced in the United States, by States, where smelted, 1937–41, in short tons

Year	Arkansas	Idaho	Illinois	Montana	Oklahoma	Pennsylvania	Other States [1]	Total	
								Short tons	Value
1937	25,799	22,831	73,151	94,680	96,153	175,275	69,015	556,904	$72,398,000
1938	20,476	15,634	68,167	77,638	68,224	139,897	56,305	446,341	42,849,000

1941	44,045	39,285	121,921	176,406	105,885	222,486	111,992	822,020	123,303,000

[1] Texas and West Virginia.

Secondary zinc.—In addition to the redistilled secondary slab zinc (unalloyed) already reported herein, some remelted slab is produced, and a large quantity of secondary zinc is recovered each year in the form of alloys, zinc dust, zinc pigments, and zinc salts. Additional information on secondary zinc is given in the chapter on Secondary Metals—Nonferrous.

Byproduct sulfuric acid.—Sulfuric acid made from the sulfur dioxide gases produced in roasting zinc blende (sphalerite) is an important byproduct of zinc smelting. To utilize a larger proportion of their acid-producing capacity, some plants also consume large quantities of sulfur. The production of sulfuric acid at zinc blende roasting plants from 1937 to 1941 is shown in the following table.

Sulfuric acid (60° B. basis) made at zinc blende roasting plants in the United States, 1937–1941

Year	Made from zinc blende [1]		Made from sulfur		Total [1]		
	Short tons	Value [2]	Short tons	Value [2]	Short tons	Value [2] Total	Value [2] Average per ton
1937	542, 356	$5, 060, 181	151, 090	$1, 409, 670	693, 446	$6, 469, 851	$9. 33
1938	466, 879	4, 253, 268	30, 996	282, 373	497, 875	4, 535, 641	9. 11
1939	528, 872	4, 765, 137	102, 663	924, 993	631, 535	5, 690, 130	9. 01

[1] Includes acid from foreign blende. [2] At average of sales of 60° acid.

Rolled zinc.—Production of rolled zinc increased 21 percent in 1941, and the average value advanced 14 percent (from $0.100 in 1940 to $0.114 in 1941). Some mills that fabricate their rolled zinc into various finished products remelt and reroll the resulting scrap. The scrap thus treated in 1941 amounted to 14,586 tons, a 43-percent gain over 1940. The zinc lost in such waste products as skimmings, dross, and pot losses totaled 1,838 tons in 1941, an amount equivalent to about 2.6 percent of the net production of rolled zinc (the same ratio as in 1940). Zinc purchased for rolling in 1941 comprised 34 percent High Grade, 29 percent Brass Special, 19 percent Intermediate, 14 percent Selected, and 4 percent Prime Western. These figures compare with the 1940 figures of 16, 41, 22, 5, and 16 percent, respectively. The increased use of the higher grades of zinc continues the trend in this direction noted in 1940 and probably reflects the gain in production of the higher grades of zinc during 1941 plus their increased use in rolled products in the expanded national defense program. Stocks of slab zinc on hand at rolling mills were about 5,200 tons (revised figure) at the beginning and 3,336 tons at the end of the year.

Rolled zinc produced and quantity available for consumption in the United States, 1940–41

[1] Revised figures.
[2] Figures represent net production. In addition, 10,183 tons of strip and ribbon zinc in 1940 and 14,586 tons in 1941 were rerolled from scrap originating in fabricating plants operated in connection with zinc rolling mills.
[3] Figures cover January to September, inclusive.
[4] Figure not available for publication.

Zinc dust.—Production of zinc dust in 1941 advanced to the highest level in the history of the industry and was 18 percent above the previous record established in 1940. The zinc content of dust ranged from 94.0 to 99.0 percent and averaged 97.7 percent.

The largest present use for zinc dust is in the manufacture of chemicals consumed in the process of printing and dyeing textiles. These chemicals, for the most part, act as reducing and bleaching agents. Other uses of zinc dust in approximate order of importance are: The metallurgical uses, including precipitation of gold, silver, and other heavy metals and production of cadmium; the sherardizing of iron; and the production of zinc paints. Some miscellaneous uses include chemicals (other than those mentioned above), manufacture of ceramics, refining of lubricants, production of oil-well drilling compounds, pipe-joint compounds, soot removers, and smoke screens, and in the Schori process of metal spraying. The last-named use is increasing in this country, and the chemical use in smoke screens undoubtedly will gain sharply because of the war.

Zinc dust is manufactured principally from galvanizers' dross, and in 1941 more than three-quarters of the total produced came from this one source. The rest of the production was from ore, metallic zinc, die-cast scrap, and numerous miscellaneous scrap zinc items, and as a byproduct of zinc refining.

Zinc dust[1] *produced in the United States, 1937–41*

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average per pound			Total	Average per pound
1937	15,242	$2,587,577	$0.085	1940	20,731	$3,404,970	$0.082

1939	16,835	2,367,861	070				

[1] All produced by distillation.

Zinc pigments and salts.—The principal zinc pigments are zinc oxide and lithopone, and the principal salts are the chloride and sulfate. These products are manufactured from various zinciferous materials, including ore, metal, and secondary substances. Details of the production of zinc pigments and salts are given in the chapter on Lead and Zinc Pigments and Zinc Salts.

Mine production.—Mine production of zinc showed a general increase in the Western, Central, and Eastern States, with an over-all gain of approximately 13 percent during 1941; the advance amounted to 40,532 tons or 17 percent in the Western States, 31,030 tons or 13 percent in the Central States, and 12,495 tons or 7 percent in the Eastern States. Oklahoma continued to be the principal producer in the country by a wide margin, contributing more than half of the yield from the Central States which supplied 37 percent of the total mine production in 1941. The increased output in this area, as well as for the entire country, can be attributed directly to the ever-increasing demand, coupled with the continued higher level of prices. As in 1940, the Tri-State (or Joplin) region supplied 35 percent and Southeastern Missouri and the other Central States only 2 percent of total domestic production. Output from Arkansas and Kentucky declined during 1941.

All the Western States, except Utah, gained in production during 1941; they yielded 38 percent of the total domestic output. Idaho continued to be the largest producer in this region, with a 12-percent increase over the previous record level of 1940. Montana again ranked second, with the largest output since 1929, and Utah maintained third place (despite a drop in production) but was closely followed by New Mexico. Output of zinc from Arizona was the largest in the history of the State and resulted from increased activity at mines producing zinc-lead ore. About 95 percent of the production from Nevada came from the Pioche district. The output from Washington gained 24 percent and was the highest ever recorded for the State; nearly all of it came from three properties at Metaline Falls.

Among the Eastern States, New Jersey continued to be the leading producer and maintained its rank as second in importance in the country, with an output higher than in any year since 1937. Output from the newly developed Hyatt mine in St. Lawrence County, N. Y., contributed to the 8-percent increase in 1941 for that State. Production in Tennessee was higher than in any previous year. Although shipments of concentrates from Virginia were greater than in 1940, actual mine production was less.

[1] Virginia included with Tennessee for 1937–39. Bureau of Mines not at liberty to publish separately.
[2] Includes a very small quantity produced elsewhere in the State.

STOCKS

Producers' stocks.—Stocks of zinc at primary reduction plants, although still at a low level, gained 26 percent by the end of 1941; the comparatively small inventories held at secondary distilling plants increased 17 percent; and total stocks also rose 26 percent. Of the total stocks on hand at the end of the year, 18,491 tons were of the higher grades of zinc (A and B) and 6,611 tons of the lower grades (C, D, and E) compared with 9,710 and 10,263 tons, respectively, at the end of 1940.

According to the American Zinc Institute, stocks of slab zinc followed a general downward trend during the first half of 1941 and reached the low point for the year at the end of June. Comparable figures for the same date in past years are not available, but the midyear stock figure was lower than any year-end total since 1913. During the latter half of 1941, stock totals advanced steadily, so that the year-end figure was somewhat higher than that at the beginning of 1941.

Stocks of zinc on hand at zinc-reduction plants in the United States at end of year, 1937–41, in short tons

	1937	1938	1939	1940	1941
At primary reduction plants	79, 144	157, 511	83, 728	19, 212	24, 212
At secondary distilling plants	1, 969	1, 915	2, 555	761	890
	81, 113	159, 426	86, 283	19, 973	25, 102

Stocks of zinc ore (60-percent concentrates) in the Tri-State district (as reported by the Tri-State Zinc and Lead Ore Producers' Association) on December 28, 1940, totaled about 2,800 short tons with a drop to 1,200 tons on January 4, 1941, as shipments continued to increase over production. Production began to gain and by February 22 exceeded shipments, with a resultant advance in stocks to 6,500 tons. This was followed by a sharp initial drop and a subsequent gradual falling off of stocks to 4,900 tons by the end of the first quarter (March 29).

During the second quarter of 1941, stocks first rose to 6,100 tons on April 19 and then showed a general slight downward trend to 5,000 tons on June 28. In this same period, production for the most part exceeded shipments; but by July 5 shipments greatly exceeded production, and stocks dropped to 3,500 tons. Following this midyear low, stocks climbed steadily (with but one notable decrease—in the latter part of August) to 9,300 tons on October 11—the peak for 1941. A subsequent sharp gain in shipments, with continued excess over slightly rising production, caused a rapid depletion of stocks to 2,900 tons on November 29, followed by a gain to 3,800 tons on December 27; however, a marked rise in shipments, accompanied by a slight decrease in production, resulted in stocks dropping to 1,500 tons on January 3, 1942—the lowest point reached since January 4, 1941.

Data on stocks of metallic zinc outside the United States continue to be unavailable, owing to the disruption of international trade in zinc ore caused by the war.

Consumers' stocks.—The monthly survey of consumer stocks, first made by the Bureau of Mines in September 1940, was continued throughout 1941. In the following table the totals, by months, from

December 1940 through June 1941 are based upon a canvass of approximately 300 companies with an estimated industrial coverage of about 90 percent at the first of the year. In August the survey was expanded to include more than 500 respondents, representing over 95 percent of the consuming industry; stock totals were recorded upon this basis beginning July 31.

Consumers' stocks of slab zinc at plants at month's end, December 1940 to December 1941, by industries, in short tons [1]

	Galvanizers	Die casters	Brass mills	Zinc rolling mills	Oxide plants	Others	Total
1940:

December	31,508	9,320	19,049	3,569	164	1,672	65,282

[1] Based upon canvass of approximately 300 companies from January through June, expanded to 520 companies beginning July 31.

In addition to the zinc recorded in the foregoing data on physical inventories at plants, several thousand tons were in transit and held for redistillation at the end of each month. The total of this additional metal ranged from as low as 10,530 tons to as high as 15,924 tons for month-ends from December 31, 1940, to December 31, 1941, with an average of about 13,200 tons a month for the year.

Although the monthly stock data do give a general picture, the results for July through December are not directly comparable with preceding months, because of variance in coverage and certain changes in industrial classification. These differences are indicated by the following table, which gives the final stock totals for the beginning and end of 1941, based upon an annual consumer survey for the calendar year 1941. Total inventories decreased 11 percent.

Consumers' stocks of slab zinc at plants at the beginning and end of 1941, by industries, in short tons [1]

	Galvanizers	Die casters	Brass mills	Zinc rolling mills	Oxide plants	Others	Total
December 31, 1940	34,903	13,522	20,412	5,251	767	1 760	76,615
December 31, 1941	33,506	9,846	19,069	3,371	319	1,977	68,088

[1] Based upon canvass of approximately 600 companies.

DOMESTIC CONSUMPTION

New supply.—A complete picture of the supply of new zinc available for consumption in 1941 cannot be published, owing to the confidential nature of foreign trade information since September 1941. In the following table the trend of supply is shown for the 4 years,

1937–40, but no attempt has been made to total the incomplete 1941 statistics. In 1941 imports that affect the total supply and exports that largely determine withdrawals are listed only for January to September, inclusive.

In addition to primary zinc, redistilled secondary metal was available for consumption in 1941. Allowing for a slight increase in stocks at secondary smelters, the supply of this material available to consumers totaled 59,374 tons.

Primary slab zinc available for consumption in the United States, 1937–41, in short tons

	1937	1938	1939	1940	1941
Supply:					
Stock at smelters Jan 1	55,500	79,144	157,511	83,728	19,212

[1] General imports.
[2] Figures cover January to September, inclusive
[3] Figures not available for publication.
[4] Not separately recorded, estimated.

Consumption.—The survey by the Bureau of Mines of zinc consumers for the calendar year 1941, mentioned earlier in this chapter under the heading Consumers' Stocks, showed that a record total of 827,435 tons of zinc actually was consumed in 1941 by approximately 600 companies, representing virtually 100 percent of the consuming industry. In comparison, a similar survey for 1940 gave a consumption total of about 733,000 tons. Receipts of zinc by consumers in 1941 totaled 818,908 tons, and the rest was supplied by an 8,527-ton withdrawal from consumers' inventories. A break-down of the total consumed, by industrial groups and principal uses in each group, was obtained for 1941 for the first time. These figures are given in the following tabulation, but no comparison can be made with previous years.

Consumption of slab zinc in the United States in 1941, by industries, in short tons[1]

Galvanizing:[2]		Die-casting alloy	150,853
Sheets	129,028	Rolled and ribbon zinc	72,049
Tubes and pipe	69,749	Zinc oxide	16,128
Wire	41,408		
Wire cloth	11,307	Other uses	
Shapes[3]	99,362	Slush castings	751
		Wet batteries	1,767
	350,854	Desilvering lead	1,431
		Miscellaneous[4]	5,564
Brass products:			
Sheets, tubes, etc	195,714		9,513
Ingots	9,497		
Castings	4,509	Total consumption: All uses	827,435
Miscellaneous	18,318		
	228,038		

[1] Based upon canvass of approximately 600 companies.
[2] Includes zinc used in electrogalvanizing but excludes sherardizing
[3] Includes pole-line hardware, hollow ware, chains, and miscellaneous articles not elsewhere mentioned
[4] Includes slab zinc used in manufacture of zinc dust.

The estimated industrial use of primary and secondary zinc, as calculated by the American Bureau of Metal Statistics, cannot be directly compared with the Bureau of Mines consumption figures for 1941 because the results were attained by separate methods and certain data are subject to different interpretation. Nevertheless, the figures in the following table are particularly valuable as they show the indicated trend over a period of several years.

Estimated industrial use of zinc in the United States, 1937–41, in short tons [1]

Purpose	1937	1938	1939	1940	1941
Galvanizing:					
Sheets	139,000	108,500	147,500	147,700	138,500
Tubes	37,000	29,300	43,300	51,200	55,000
Wire	33,000	23,600	33,000	33,900	37,100
Wire cloth	7,000	5,600	7,700	8,400	8,600
Shapes [2]	40,000	31,000	43,500	45,800	60,800
	256,000	198,000	275,000	287,000	300,000
Brass making	169,000	102,000	175,000	232,000	313,000
Rolled zinc	58,000	46,000	62,000	58,000	69,000
Die castings	88,000	48,000	84,000	116,000	125,000
Other uses [3]	39,000	27,000	30,000	26,000	24,000
	610,000	421,000	626,000	719,000	831,000

[1] American Bureau of Metal Statistics, Year Book, 1941.
[2] Includes pole-line hardware, hollow ware, chains, and all articles not elsewhere mentioned
[3] Includes slab zinc used for manufacture of French oxide, zinc for wet batteries, slush castings, the desilverization of lead, wire for metalizing, etc., and sundries.

The quantity of zinc used by industry in 1941, as estimated by the American Bureau of Metal Statistics, was 16 percent higher than the previous record established in 1940. According to the data in the foregoing table, all the principal uses indicate increases in 1941—galvanizing 5 percent, brass making 35 percent, and die castings 8 percent. Galvanizing took 36 percent of the total tonnage in 1941 compared with 40 percent in 1940 and 44 percent in 1939. This item includes zinc used in electrogalvanizing and that used in sherardizing; the former increased from 6,071 tons in 1940 to 7,594 tons in 1941, and the latter from 618 to 944 tons. An incomplete break-down of the zinc used in rolled products in 1941 (1940 figures in parentheses) included 20,975 tons (20,985) in battery cans, 3,600 (1,904) in boiler plate, and 449 (426) in brake lining. The remaining tonnage was distributed for glass jar tops, photoengraving sheet, and automobile manufacture and for miscellaneous uses or export. The chief item in "Other uses" is the slab zinc employed in making French-process zinc oxide.

PRICES

Despite the ever-increasing demand for zinc, from January through September the price of Prime Western at St. Louis continued at the 7.25-cent-a-pound rate established September 24, 1940. In an effort to expand output from marginal producers, the Office of Price Administration raised the base price on October 9, 1941, from 7.25 to 8.25 cents, where it remained for the rest of 1941 The price of zinc

concentrates quickly followed with a rise of \$6.70 to \$55.28 per ton for 60-percent zinc concentrates in the Tri-State market, the highest reached in 15 years. The average quoted price for zinc in 1941 was 7.48 cents compared with 6.34 cents in 1940.

Information on London Metal Exchange dealings, which were suspended at the outbreak of the war, continued to be unavailable during 1941. On December 18, 1939, the Nonferrous Metal Control for the United Kingdom fixed the price of zinc at £25 15s., delivered consumers, duty paid, for foreign zinc, and £26 10s., for domestic metal. These established prices did not change during 1941.

[1] American Metal Market quotes average prices of High Grade and Brass Special as follows: High Grade (f. o. b. New York)—1937, 7.76 cents; 1938, 5.74 cents; 1939, 6.16 cents; 1940, 7.38 cents; 1941, 8.48 cents. Brass Special (f. o. b. East St. Louis)—1937, 6 62 cents; 1938, 4.71 cents; 1939, 5.22 cents; 1940, 6.44 cents; 1941, 7.68 cents.

ZINC-REDUCTION PLANTS

Zinc smelters.—No changes took place during 1941 in the number of active and idle zinc smelters; as in 1940, there were 17 active plants and 1 idle plant. Of those active, 13 continued to operate with horizontal retorts exclusively, 1 with both horizontal and vertical retorts, 2 with large vertical retorts exclusively, and 1 with electrothermic furnaces. The total number of retorts reported at the active horizontal-retort primary plants was 68,552, a 10-percent increase over the 62,368 recorded for December 31, 1940. Of the total retorts reported, 65,969 were in use, a 19-percent increase over the 55,328 in operation at the close of 1940. Although this active equipment represented 96 percent of the total at the regular plants, smelting operations were at usable capacity throughout 1941; the remainder represents a rapidly decreasing amount of equipment that has been idle for some time and is being replaced or reconditioned, plus a certain percentage that was closed down for necessary repairs. At the end of 1941, 800 new retorts were under construction. The 14 new large vertical retorts under construction at the end of 1940 were completed during 1941, bringing the total reported to 66, of which 64 were in use at the year's end.

Many primary smelters treat scrap as well as ore. Horizontal-retort plants at Beckemeyer and Sandoval, Ill., and graphite-retort plants at Trenton, N. J., Philadelphia and Bristol, Pa., Wheeling, W. Va., Tottenville, N. Y., and Fairfield, Ala., handle scrap exclusively. Graphite retorts were also operated during 1941 by Morris P. Kirk & Son, Inc., Los Angeles, Calif., and the New England Chemical Works, Putnam, Conn.; both concerns use scrap exclusively. The Torrance (Calif.) plant of the Pacific Smelting Co., Ltd. uses small clay retorts as well as graphite retorts for treating secondary materials. Although no units were reported under construction at secondary plants during 1941, additional graphite retorts are planned for future installation at Fairfield and Philadelphia.

Electrolytic plants.—Four electrolytic plants were in operation during 1941 compared with three in 1940. The plant of the American Zinc Co. of Illinois at East St. Louis, Ill., which opened in May 1941, operated at full capacity thereafter during the year, and construction work was planned for doubling the output. The plant of the Sullivan Mining Co. at Kellogg, Idaho, made full use of its capacity. The Anaconda Copper Mining Co. plant at Anaconda, Mont., operated to

full extent, and the Great Falls plant ran at near capacity; both plants increased their capacity over 1940, and additional plant facilities were planned for 1942. At the four plants, 2,502 cells out of a total of 2,526 were in use at the end of 1941 compared with 2,204 out of 2,228 at three plants at the end of 1940; no new cells were reported under construction at the end of the year, but 348 additional cells were planned for 1942. The American Smelting & Refining Co. electrolytic zinc plant at Corpus Christi, Tex., which was begun in 1940, was still under construction at the end of 1941 but should be ready to operate in 1942 with an annual capacity of 25,000 tons of zinc.

FOREIGN TRADE [3]

Imports.—The following tables give zinc total imports (general) in ore and blocks, pigs, or slabs into the United States, 1939–40, and from January through September 1941; imports for consumption, 1937–40 and 9 months of 1941; and a record of bonded warehouse inventories, 1937–41.

Zinc imported into the United States in ore, blocks, pigs, or slabs, 1939–41, by countries, in short tons [1]

Country	1939	1940	1941 (Jan.-Sept.)
Ore (zinc content):			
Argentina	1, 544	6, 723	5, 320
Australia		1, 749	8, 933

1938	51, 058, 373
1939	20, 295, 817
1940	184, 442, 754
1941 (Sept. 30)	279, 092, 943

[1] Includes zinc ore (zinc content) and zinc blocks, pigs, old, and sheets.

As imports in 1941 are listed for only 9 months no direct comparisons can be made with 1940 totals, but statistics for the January–September period do give an interesting picture of the trend since 1940. By September 30, imports of zinc ore and concentrates were

[3] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

greater than the 1940 total. Mexico remained the chief source, with shipments amounting to 51 percent of the total, followed by Canada and Peru; although figures for all three countries indicate that totals for the year exceeded those for 1940, Peru shows the greatest gain. Increased amounts came from Australia and Bolivia; but imports from Newfoundland and Labrador in the 9 months declined appreciably, and none were reported from Chile. A substantial tonnage was obtained from Argentina, as well as from Belgian Congo and Spain. The rapid rise in the amount of zinc remaining in warehouse (from 184,442,754 pounds at the end of 1940 to 279,092,943 pounds on September 30, 1941) is due largely to the preponderance of total imports (general) over imports for consumption.

Before 1940, total (general) imports of slab zinc very closely approximated imports for consumption, whereas in 1940 total imports were higher than imports for consumption by about 6,000 tons. Upon the basis of 9-months' totals the reverse is indicated for 1941; the 30,995 tons imported for consumption during this period (12-months' figures for 1940 in parentheses) included 23,085 tons (2,647) from Mexico, 6,704 tons (6,877) from Canada, and the rest from French Indochina, Australia, and Peru. In comparison, the 9-months' total (general) imports of slab zinc—25,212 tons—included 17,362 tons (8,948) from Mexico and 6,704 tons (6,938) from Canada.

Zinc imported for consumption in the United States, 1937–41, by classes

Year	Ores (zinc content)		Blocks, pigs, or slabs		Sheets		Old, dross, and skimmings [1]		Zinc dust		Total value [2]
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	
1937	3,345	$177,457	37,208	$3,852,884	231	$30,398	678	$70,460	69	$6,169	$4,137,368

1941 [3]	66,976	2,421,632	30,995	2,841,071	71	14,029	412	28,065	68	12,301	5,317,098

[1] Includes dross and skimmings as follows—1937. 560 tons, valued at $59,635, 1938. None reported, 1939 30 tons, $1,918, 1940· 356 tons, $21,815, and 1941 (Jan -Sept.) 353 tons, $23,028

[2] In addition, manufactures of zinc imported as follows—1937. $828, 1938 $463, 1939 $1,545; 1940 $32, 1941 (Jan -Sept.)· $68.

[3] January to September, inclusive

Exports.—The value of exports in 1941 (January–September) of zinc ore and manufactured articles containing zinc of foreign and domestic origin (excluding galvanized products, alloys, and pigments) amounted to $9,557,706 compared with $11,302,228 in the full year 1940. The maintenance of this high over-all value was due to increased prices. Slabs, plates, or blocks continued to be the largest export group. In addition to the items shown in the accompanying tables, considerable zinc is exported each year in brass, pigments, chemicals, and galvanized iron and steel. The American Bureau of Metal Statistics estimates that 14,300 tons of zinc were exported in galvanized products from January through September 1941. Export data on zinc pigments and chemicals are given in this volume in the chapter on Lead and Zinc Pigments and Zinc Salts. Much of the zinc used in the manufacture of such products is of foreign origin, and when they are exported a draw-back of 99 percent of the import duty is paid on the

basis of zinc contained in the finished product. For the 9-month period in 1941, draw-back was paid on 22,777 tons of zinc, of which 7,638 tons had been imported as slabs and 15,139 tons as ore. Totals for preceding years were: 1940, 19,306 tons; 1939, 16,213 tons; 1938, 11,550 tons; 1937, 9,253 tons; and 1936, 8,909 tons.

In the following table on exports of slab and sheet zinc by countries of destination, the figures only for the first quarter of 1941 are given to show the general distribution. The influence of the Lend-Lease program in 1941 is indicated by the large tonnage exported to the United Kingdom during the 3-month period.

Slab and sheet zinc exported from the United States, 1938–40, and January to March, 1941, by destinations, in short tons

WORLD ASPECTS OF ZINC INDUSTRY

A perspective of the zinc situation throughout the world in 1941 shows continuation of the abnormal conditions that prevailed during 1940.

Although official data are lacking, the serious need for zinc for military and civilian use indicates that world production and consumption of this metal were greater in 1941 than ever before. Some of the details by countries, where such information is available, are discussed in the following pages. Owing to the serious lack of data for 1940 and 1941, the table showing world smelter production has been omitted.

REVIEW BY COUNTRIES

Argentina.—Production of zinc concentrates in Argentina in 1941 amounted to 66,010 metric tons containing about 36,300 tons of zinc, only slightly below the 1940 total of 66,384 tons containing approximately 37,000 tons of zinc.. The Aguilar mine of the St. Joseph Lead Co. in the Province of Jujoy is still virtually the only producer. This and other smaller mines supply concentrates for the Puerto Vilelas smelter. During 1940 a large percentage of the output of concentrates accumulated as stocks as the result of difficulty in disposing of them. In June 1941 the United States, through the Metals Reserve Co., purchased the greater part of such stocks on hand. Reportedly this purchase amounted to 100,000 long tons of concentrates containing 42,500 long tons of recoverable zinc.

Australia.—Base-metal production statistics for Australia for 1941 are not available. A prominent feature in development work at the various zinc properties is the use of diamond drilling. Late in 1941 diamond drilling at New Broken Hill gave evidence of a reversal of pitch of the present ore body, which, if true, means that the main body to the south will be shallower. This would have an important bearing on future mining practice. Operations at Broken Hill during 1941 continued in the usual efficient manner; at North Broken Hill the main feature of the mining operations has been the continued success attending extraction of ore from lode pillars, as 23.8 percent of the ore mined in the North section during the last operating period was won from this source. Ore reserves were estimated at 5,232,000 long tons as of June 30, 1941. Broken Hill South, Ltd., introduced a hydraulic system of stope filling Lower-grade crude ore treated at this property during 1941 was offset by improved metallurgy resulting in the following recoveries: Lead, 96.1 percent; silver, 92.2 percent; and zinc, 89.1 percent. The latest available figures for the Zinc Corporation, Ltd., indicate ore reserves of about 3,650,000 long tons.

The Broken Hill Associated Smelters at Port Pirie are reported to be conducting research as to the feasibility of recovering zinc from accumulated blast-furnace slag containing 15.78 percent zinc and a minor amount of lead. Mt. Isa Mines, Ltd., Queensland, continued to make a steady output of zinc concentrates during 1941. Estimated sulfide ore reserves, as of June 30, 1941, have been reported to total 8,775,300 tons averaging 8.65 percent zinc.

Bolivia.—Mine production of zinc (content in ore) in Bolivia amounted to only 6,065 metric tons in 1941 compared with 12,197 tons in 1940. Bolivian output of zinc ore and concentrates is comparatively small, and no apparent reserve stocks are carried.

Brazil.—The zinc-bearing zone of the Iporanga district, São Paulo, is the most important in Brazil. Reserves of sphalerite and calamine ore, containing 31 to 36 percent zinc and estimated as amounting to 30,000 metric tons, have been reported near the Apiai lead-silver

deposits. Other deposits occur in Minas Gerais at Januaria and at Morro do Bule near Curo Preto. The only zinc currently being produced in Brazil is in the form of a byproduct from the Furnas lead-silver mine in the Iporanga district. The ore averages 7 percent lead and 17 percent zinc. The new selective-flotation mill has a daily capacity of 35 tons and produces 55-percent zinc concentrates with a recovery of 83 percent.

Burma.—Ore reserves of the Bawdwin mines, at the end of the fiscal year (June 30, 1941), were estimated at 3,130,200 tons of ore assaying 15.1 ounces of silver, 19.5 percent lead, and 12.1 percent zinc, or slightly lower both in tonnage and metal content than estimates for the previous fiscal period.

Canada.—Continued war restrictions prevent the publication of base-metal production figures for Canada. The drive for zinc output by the Consolidated Mining & Smelting Co. has resulted in a greater production of lead as well. By the end of 1941, Waite Amulet was treating about 1,500 tons of ore a day. The new 300-ton addition to the mill, in operation since October 1941, has been producing zinc for the American market. It is reported that the Hudson Bay Mining & Smelting Co. has recently installed a 10-ton pilot plant for the experimental treatment of zinc residues that have accumulated at Flin Flon since 1930. Successful operation may result in the expansion of facilities for commercial-scale treatment of about 250,000 tons of this material. By the end of 1941, mining operations had been resumed at the old Calumet Island property near Ottawa; ore reserves have been estimated at 1,300,000 tons.

Canadian zinc-ore exports continued to go largely to the United States and in the 9-month period from January through September 1941 amounted to 34,000 tons compared with the same amount in all of 1940. The United Kingdom was the chief market for slab-zinc exports, although the amount shipped to the United States during the January-September period was nearly equal to the total for 1940. The ban on exports of zinc dross, remelted zinc in slabs, or high-grade zinc scrap remained in effect throughout 1941. Measures have been taken by the Canadian Government to conserve for essential purposes all available supplies of zinc that are in demand for defense purposes. As a result of this program of curtailment, 75 percent of the estimated use of zinc in 1941 was for essential purposes and 25 percent nonessential. In comparison, the division in 1940 was 36 and 64 percent, respectively.

Mexico.—Mine production of zinc in Mexico totaled 154,996 metric tons in 1941, compared with 114,955 tons in 1940. This large increase reflects the great demand for zinc in the United States, to which approximately 84,000 metric tons (content in ore and concentrates) were exported from January through September 1941. A considerable part of this tonnage came from stock piles accumulated after the sea blockade had cut off European markets in 1939. Smelter output totaled 31,500 metric tons, a drop from the 33,400 tons produced in 1940, due largely to labor difficulties at the beginning of the year at the Rosita smelter of the American Smelting & Refining Co.

Peru.—Production of zinc concentrates in Peru during 1941 totaled approximately 40,800 metric tons, with an extractable zinc content of 23,700 tons, a marked increase over the 1940 total of 29,467 tons

containing 17,000 tons of zinc. This output is principally from the properties of the Cerro de Pasco Copper Corporation. Construction of the new 800-ton-per-day lead-zinc concentrator is progressing, but the plant is not scheduled for completion before late 1942 or in 1943. The corporation's 5-ton pilot electrolytic zinc plant operated successfully in 1940 and 1941, and erection of a commercial-size refinery of 100 tons daily capacity is under consideration.

Spain.—Little information has been available regarding the Spanish zinc industry during and following the years of the Spanish Civil War, which was concluded in 1939. It is reported that mine production of zinc in 1940 amounted to about 74,000 metric tons and that 12,300 tons of metal were produced. For 10 months of 1941, mine and metal production has been given as 60,900 and 10,400 tons, respectively. The zinc deposits of Spain are mainly in the Santander region, the principal mines being operated by the Real Compañía Asturiana de Minas.

LEAD AND ZINC PIGMENTS AND ZINC SALTS

By H. M. Meyer and A. W. Mitchell

SUMMARY OUTLINE

GENERAL SUMMARY

Expansion in the use of lead and zinc pigments, forecast in the report of this series for 1940, resulted in the establishment of several new high records for this group of commodities in 1941. The achievements were due to considerable gains in the use of litharge and red lead for storage batteries and of dry white lead, leaded zinc oxide, and others for the manufacture of paint, to outstanding advances in the use of zinc oxide for rubber manufacture, to the use of unprecedented quantities of litharge and zinc oxide in ceramics, and to record amounts of litharge used in insecticides. In 1941 consumption of black oxide or suboxide of lead, not included in the pigments totals, also rose above all previous years.

The actual demand for many products in 1941, particularly those made from metals and metallic ores, is impossible to gage. Sales of zinc and lead pigments unquestionably would have been much larger had adequate quantities of raw materials for their unrestricted manufacture been available. Moreover, the relationship of zinc, lead, and titanium pigment totals in that year undoubtedly would have been more favorable to titanium and zinc, because raw materials for these pigments were more restricted than those for the lead group

Zinc is closely related to war needs, more so than lead. Consequently, a tight situation in zinc metal and scrap for the manufacture of pigments arose early in the war. This condition affected zinc oxide more than other pigments, for more metal is used in its manufacture than in any other zinc pigment. In recent years the use of scrap in making zinc oxide had risen so that roughly equal quantities of zinc oxide and lithopone (in terms of zinc content) were made from scrap materials. More than half of the zinc oxide manufactured, however, is made direct from ore. Although zinc oxide sales increased 31 percent during 1941, the zinc content of oxide made from metal and scrap actually decreased more than 5,000 tons; output from ores, meanwhile, increased 29,000 tons in terms of zinc content. As early

as June 10, 1941, zinc was placed under full priority control by the Office of Production Management (now the War Production Board). Producers of zinc oxide were ordered to set aside in July an amount equivalent to 10 percent of their May output for emergency allocation by the Director of Priorities. From then until the end of the year the amount to be set aside ranged from 10 percent for some months to none for others; the percentage usually applied to the second preceding month.

Pig lead supplies appeared to be satisfactory at the beginning of 1941; however, the greatly expanded use of this metal for war and civilian purposes, partly as a substitute for scarcer materials, brought noteworthy changes in this favorable position as the year progressed. Consequently, lead was placed under full priority control in October.

In 1941 lead pigments, as a group, made a better showing than zinc pigments in relation to 1940, as the total quantities sold advanced 37 and 27 percent, respectively. In relation of 1941 to averages for 1925–29, however, zinc pigments performed better, having risen 10 percent compared with 1 percent for lead pigments. Failure of white lead in oil to maintain its relative position caused the poorer showing of lead pigments in the latter comparison.

The titanium pigments group, competitors in the white pigment field, experienced unprecedented activity again in 1941.

Average quoted prices for lead and zinc pigments were generally higher in 1941 than in 1940, and the average values reported to have been received by producers confirmed the trend of quotations.

Salient statistics of the lead and zinc pigments industry of the United States, 1925–29 (average) and 1937–41

	1925–29 (average)	1937	1938	1939	1940	1941

[1] Figures cover January to September, inclusive.

PRODUCTION

Sales have more significance in this report than production, owing to lack of data on stocks at the beginning and end of the year. In some instances materials reported as one commodity for production have been sold later under another classification. Therefore, sales figures afford a more accurate guide to the pigments actually going into consumption. To prevent duplication, care is necessary even in handling sales figures. Some pigments reported as sales of finished products at one plant actually are used by other plants as an intermediate product in the manufacture of another pigment covered by the lead and zinc pigments canvass. Basic lead sulfate consumed in the manufacture of leaded zinc oxide is the principal problem in this connection, but it is not the only one. Production figures are employed in this report only in calculating the metal content of pigments and salts in the section on Raw Materials Used in Manufacture of Lead and Zinc Pigments and Zinc Salts. Pigments used by producers in manufacturing products at their own plants are included as sales.

The total value of sales of lead and zinc pigments showed a 40-percent rise, from $61,375,000 in 1940 to $85,782,000 in 1941. This noteworthy increase was due to advances in sales of all pigments and to gains in average values received by producers for virtually all items.

Lead pigments.—The lead pigments that in 1941 rose above all previous years in sales were litharge, red lead, and white lead (dry); these commodities gained 36, 25, and 26 percent, respectively, over previous high records established in 1940, 1929, and 1925. On the whole, price quotations in 1941 did not exceed the higher levels of the 1940 range; but, in general, they were above the lower levels, so that average quoted prices topped those of the earlier year. In 1941 most of the lead pigments made gains in average value received by producers. Consequently, although lead pigments showed a notable rise (37 percent) in total quantity the increase (43 percent) in their total value was even greater.

White lead in oil advanced 16 percent in 1941 but lagged behind all other pigments. Gains in sales of white lead (dry) brought this pigment up to 94-percent of the quantity of the paste product, the highest proportion it has ever attained in this relationship.

Lead pigments sold by domestic manufacturers in the United States, 1940–41

Pigment	1940			1941

[2] Orange mineral included with red lead.

Zinc pigments and salts.—Sales of leaded zinc oxide established another new high record in 1941, and those of the lead-free class were the largest since 1929; the total of both grades had never been exceeded before. Lithopone sales, although not attaining a new peak, had been higher only from 1927 to 1929, inclusive. The sharp rise in the use of ore in the manufacture of zinc oxide was due primarily to the difficulty in obtaining adequate supplies of zinc metal and scrap in 1941. The average quoted price for lithopone in 1941 was above the range for 1940, but, in general, prices for various grades of zinc oxide were at or close to the top of the ranges for 1940. Producers reported receiving higher average values for all pigments during 1941.

[1] No canvass.
[2] Figures represent production.
[3] Data not available.

Complete data covering the production of zinc chloride in recent years are not available owing to the absence of a reliable report from one producer, whose output is believed to have been large.

Sales of zinc sulfate established a second successive high in 1941—61 percent above the previous record, attained in 1940.

CONSUMPTION BY INDUSTRIES

White lead.—Total sales of white lead gained 40 percent over 1940, and the dry variety established a new high record. White lead in oil did not make a good showing in relation to other prosperous years for the pigments industry.

Normally about 95 percent of the white lead sold is used in the manufacture of paint. For the past 2 years, the percentage has been closer to 90 percent, although some of the quantities shown under "Other" may rightfully belong under the paint classification.

Early in 1942, the Federal Specification Board approved several Emergency Alternate Specifications, including one to cover three regular specifications, namely: TT–P–36a, Lead-Zinc; TT–P–101a, Titanium-Zinc and Titanium-Zinc-Lead; TT–P–156, Basic Carbonate White Lead. A single emergency paint to take the place of all three will be designated E–TT–P–101a, Titanium-Zinc and Titanium-Zinc-Lead, Outside, Ready-Mixed White Paint. Although the title implies two types, only the titanium-zinc-lead type is specified. It covers light tints as well as the white product. The composition requirements are: Pigment, minimum 63 percent, consisting of

titanium dioxide, minimum 10 percent; zinc oxide, minimum 24 percent; white lead, minimum 24 percent; sum of zinc oxide and white lead, minimum 48 percent; inert pigments, maximum 40 percent. A semi-chalk-resisting type of titanium dioxide is required.

Distribution of white lead (dry and in oil) sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Paint	93, 580	95, 018	92, 380	73, 137	100, 665
Ceramics	2, 506	1, 918	1, 767	3, 029	3, 704
Other	2, 127	3, 277	4, 282	4, 396	8, 631
	98, 213	100, 213	98, 429	80, 562	113, 000

Basic lead sulfate.—The outstanding use of basic lead sulfate is also in the manufacture of paint; 90 percent of the total was sold for that purpose in 1941. The increasing use of this pigment in making leaded zinc oxide has been noted in earlier chapters of this series. The practice assumed record-breaking proportions in 1941, when 12,000 tons were so used compared with the previous peak of 7,700 tons in 1939. These quantities are included in the totals for leaded zinc oxide but not in those for basic lead sulfate.

Distribution of basic lead sulfate sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Paints	8, 255	5, 024	5, 170	5, 593	9, 285
Rubber	213	91	140	128	200
Storage batteries	6	3	4	4	8
Other	148	683	224	475	877
	8, 622	5, 801	5, 538	6, 200	10, 370

Red lead.—Sales of red lead were record-breaking in 1941; they exceeded the previous peak in 1929 by 25 percent and fulfilled the promise of increased use made when it became evident that a tremendous expansion in plant construction to supply materials for war purposes would develop. Although sales to makers of storage batteries continued to represent the larger part of the total, they did not advance in the same ratio as sales to manufacturers of paints,which gained 68 percent.

An Emergency Alternate Federal Specification for Red-Lead-Base Ready-Mixed Paint, E–TT–P–86, changed the specifications for this paint to: Pigment, red lead (95 percent grade), minimum 40 percent; red iron oxide (70 percent Fe_2O_3), minimum 20 percent; zinc oxide, minimum 10 percent; extenders, remainder (magnesium silicate, aluminum silicate, silica, or mixtures).

Distribution of red lead sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Storage batteries	20, 275	19, 057	24, 709	26, 718	27, 405
Paints	10, 440	8, 698	11, 421	11, 949	20, 130

	33, 931	30, 183	39, 976	42, 200	53, 838

Orange mineral.—This pigment is produced in very small quantities. Ink manufacture took the principal amount in 1941.

Distribution of orange mineral sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Ink manufacture	76	20	64	51	98
Color pigments	51	94	40	18	26
Other	79	13	27	68	122
	206	127	131	137	246

Litharge.—Sales of litharge made a new high record in 1941, owing largely to the sharp advance in its use for storage batteries (the largest consuming industry) and to noteworthy increases in sales to makers of ceramics, chrome pigments, and insecticides. Each of these industries took more litharge than ever before. On the other hand, its use in rubber and varnish manufacture, although greater than in 1940, had been exceeded in earlier years. Black oxide or suboxide of lead used by storage-battery manufacturers established successive peaks in 1939, 1940, and 1941. The total for 1941 was 61,000 tons compared with 53,000 in 1940 and 45,000 in 1939. Sales of black oxide are not included in Bureau of Mines totals for litharge.

Distribution of litharge sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Storage batteries	32,228	32,514	39,754	38,303	49,847

Linoleum	264	231	226	418	647
Other	4,925	3,011	3,558	3,082	6,289
	83,902	68,711	89,518	89,841	122,280

Zinc oxide.—Although zinc oxide sales were 31 percent above those in 1940, unlike some of the pigments that made new highs in 1941, they were exceeded by the totals for 1925 and for each of the 3 years 1927, 1928, and 1929. The demand for zinc oxide in the manufacture of rubber and ceramics broke all records. Gains were also registered in sales for paint manufacture and floor coverings and textiles, but the quantities did not represent the largest ever sold for these purposes. The inadequacy of zinc metal and scrap supplies in 1941 caused a sharp downturn in the proportion of French-process zinc oxide made in that year, and only 24 percent of the total was manufactured by that method; 76 percent was American-process zinc oxide. These percentages represent changes from the 36 and 64 percent, respectively, for 1940 and the 41 and 59 percent for 1939. It is impossible to say what zinc oxide sales would have been if enough zinc had been available to meet requirements for the manufacture of this product.

Provisions for a zinc oxide monthly pool, for allocation by the Director of Priorities, are discussed in the opening section of this

report. The maximum prices for various grades of zinc oxide, which the Office of Price Administration requested manufacturers to maintain beginning January 1, 1942, are discussed in the price section of this report.

A new plant for the manufacture of zinc oxide by direct flash fuming zinc concentrates was completed and put in operation by the Eagle-Picher Mining & Smelting Co. in January 1941 at Galena, Kans.; a second unit that doubled the capacity of the plant was constructed and went into production early in July. Production of zinc oxide was begun during the year by the Gulton Metals Refining Co. at Metuchen, N. J.

Distribution of zinc oxide sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Rubber	67,061	46,266	70,187	70,979	90,429
Paints	27,987	20,884	25,334	23,268	30,304
Ceramics	5,216	4,908	6,572	6,352	8,596
Floor coverings and textiles	9,019	3,030	5,641	4,752	6,991
Other	5,369	4,041	6,818	7,862	12,513
	114,652	79,129	114,552	113,213	148,833

Leaded zinc oxide.—This increasingly popular pigment continued to advance in 1941, and sales reached new heights—68,920 tons, or 52 percent above the previous high record for 1940. One factor in the large increase during 1941 is that virtually all the zinc content of this pigment comes from zinc ores and concentrates; consequently, gains in its production placed no strain on tight supplies of zinc metal and scrap. As usual, paint manufacturers took nearly all the leaded zinc oxide sold. The total shown for leaded zinc oxide in 1941 includes 12,000 tons of basic lead sulfate used to increase the lead content of the product; this tonnage is excluded from the basic lead sulfate totals to avoid duplication in reporting data for metals.

Distribution of leaded zinc oxide sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Paints	39,584	37,348	41,519	44,341	67,472
Rubber	97		1		1
Other	662	868	1,164	1,021	1,447
	40,343	38,216	42,684	45,362	68,920

Lithopone.—Lithopone statistics are reported upon the basis of the regular lithopone content of high-strength lithopone plus normal lithopone sold as such; before 1936, they were upon the basis of standard-strength plus high-strength product. Sales in 1941 were 16 percent above those in 1940 and with the exception of 1927–29 were the largest on record. Paints, varnish, and lacquers take the principal part of the total lithopone sold, and sales to such users increased 13 percent in 1941; this use took about 80 percent of the total in several years but only 77 percent in 1940 and 75 percent in 1941. Floor coverings and textiles have used 12 to 13 percent and rubber 2 to 3 percent of the total in recent years. Based upon somewhat

incomplete information, separation of the 1941 quantities shown in the following table for floor coverings and textiles indicates that 16,000 tons were used for linoleum and felt-base floor coverings and the remainder for coated fabrics and textiles (oil cloth, shade cloth, artificial leather, and similar products). Other sales in 1941 included 5,559 tons for paper and 2,301 tons for printing ink. Figures for an additional quantity for printing ink cannot be separated from the total figures for paints.

Plant capacity for the production of lithopone was reported to total 181,600 tons at the end of 1941.

Distribution of lithopone sales, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Paints, etc.	122,915	101,924	113,995	117,075	132,691

The use of ordinary-strength lithopone in the manufacture of titanated lithopone (which usually contains 15 percent TiO_2) reached a peak in 1937, when 19,400 tons were so used; in 1941, 14,100 tons were used for this purpose. The lithopone figures in the following table are included in the totals for ordinary lithopone in the preceding table.

Titanated lithopone produced in the United States and ordinary lithopone used in its manufacture, 1937–41, in short tons

Year	Titanated lithopone produced	Ordinary lithopone used	Year	Titanated lithopone produced	Ordinary lithopone used
1937	23,000	19,400	1940	18,100	15,200
1938	20,100	17,000	1941	16,800	14,100
1939	16,100	13,700			

Zinc sulfide.—Although zinc sulfide has been produced by four plants in the United States in recent years, one producer dominates the industry; therefore, the Bureau of Mines has not been at liberty to release data on this commodity. Only two plants were productive in 1941.

Zinc chloride.—The Bureau of Mines cannot report zinc chloride production as one producer, whose output is reputed to be large, has failed to supply reliable data.

Zinc sulfate.—Sales of zinc sulfate in 1941 exceeded by a wide margin the high record established in 1940, thus continuing the uptrend that began in 1933 and was interrupted only in 1938; the gain over 1940 was 61 percent. Of the 1941 total, 5,555 tons were indicated for chemical manufacture (including the medicinal trade), 5,170 for rayon, 3,038 for agricultural purposes, 1,422 for paints and varnish processing, 1,203 for glue manufacture, 502 for electrogalvanizing, 246 for flotation reagents, and 130 for textile printing and dyeing. The distribution of 1,935 tons was not reported.

RAW MATERIALS USED IN MANUFACTURE OF LEAD AND ZINC PIGMENTS AND ZINC SALTS

Lead pigments and zinc pigments and salts are manufactured from a variety of materials, including ore, refined metal, and such miscellaneous secondary materials as scrap and waste from various industrial processes. In 1941, 91 percent of the lead pigments were derived from pig lead and 9 percent from ore. The proportion for zinc pigments in 1941 was 74 percent from ore, 8 percent from slab zinc, and 18 percent from secondary materials.

Domestic	16,869	94,491	23,951	129,520
Foreign			290	2,464
Metal	196,235	19,421	248,674	15,463
Secondary material [2]		29,675	400	31,703
	213,104	143,587	273,315	179,150

[1] Includes also lead recovered in leaded zinc oxide.
[2] Zinc ashes, skimmings, drosses, and old metal.

The following tables give the source of the metal used in the manufacture of each pigment and salt. Pig lead is employed exclusively, either directly or indirectly, in the manufacture of white lead, litharge, red lead, and orange mineral and is used also in the manufacture of basic lead sulfate. The lead content of leaded zinc oxide made from basic zinc sulfate, which in turn was made from pig lead, is credited to pig lead in the table. Zinc oxide is the only pigment in which considerable slab zinc is used. Ore is employed in the manufacture of zinc oxide, leaded zinc oxide, lithopone, zinc sulfate, and basic lead sulfate. A substantial proportion of the zinc in lithopone and zinc chloride made in the United States is derived from secondary material. A decided increase has been noted in the quantity of secondary zinc consumed in the manufacture of zinc oxide since 1933. The relative scarcity of zinc metal and scrap in 1941 caused declines in the use of both these materials for the manufacture of zinc oxide in the face of a noteworthy gain in production of the pigment.

PRICES

The total values reported by producers for lead and zinc pigments and zinc salts are given in the tables in the first part of this report. The average reported values for all lead pigments, except white lead in oil and basic lead sulfate (blue), were above those for 1940 by $2 to $20 a ton; these two classes remained unchanged from 1940. Average price quotations for all lead pigments exceeded those for 1940, principally because they were near or at the top of the range for 1940 rather than because they actually exceeded the range for that year. Price changes for lead oxides, as usual, coincided with the price changes for the metal. White lead prices rose at the beginning of January 1941 and remained unchanged thereafter.

All values reported by producers for zinc pigments and salts were higher in 1941 than in 1940. On the whole, average price quotations also were higher than in 1940 because they clung to the higher part of the 1940 range. They were generally unchanged throughout 1941, although Pacific coast prices for lithopone, zinc oxide, and zinc

sulfide rose ¼, ½, and ½ cent a pound, respectively, in midyear. Prices for lithopone and zinc sulfide were advanced on the first day of 1941 but did not change subsequently. Zinc sulfate prices rose ½ cent a pound in June.

Range of quotations on lead pigments and zinc pigments and salts at New York (or delivered in the East), 1938–41, in cents per pound

Product	1938	1939	1940	1941
Basic lead sulfate, or sublimed lead, less than carlots, barrels	5.50- 6.50	6.25- 6.50	6.25- 6.75	6.50- 7.00

Zinc sulfate, crystals, barrels	2.65- 4.05	2.90- 3.65	2.90- 3.90	3.15- 4.40

The favorable behavior of prices for lead and zinc pigments and zinc salts, in the face of the tremendous pressure of record-breaking sales and scarcity of raw materials, was in deference to the known Government desire to avoid price advances wherever possible throughout the war emergency.

In December zinc oxide producers were requested by the Office of Price Administration to agree individually to a list of maximum prices for their product. The O. P. A.-approved ceiling prices per pound for various grades of zinc oxide delivered in bags in carlots were 7.25 cents for lead-free American process oxide, 6.75 cents for leaded zinc oxides containing 35 percent or more lead, 7.125 cents for leaded zinc oxides containing less than 35 percent lead, 9.50 cents for lead-free French process oxides other than U. S. P., and 10.50 cents for French process U. S. P. oxide. Price schedule 80 of the Office of Price Administration, effective February 2, 1942, set a maximum price of 4.25 cents per pound for the normal grade of lithopone.

FOREIGN TRADE [1]

Any discussion of foreign trade in 1941 is necessarily restricted because data for October and subsequent months are held confidential by the Department of Commerce. Incomplete figures for imports fail to indicate anything unusual in that phase of foreign trade. It is noteworthy, however, that export values for the first 9 months of 1941 exceeded those for the full year 1940 in each group covered by the following table. Lithopone continued to be the outstanding item in the export class, whereas zinc oxide led again in the relatively unimportant import class.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Value of foreign trade of the United States in lead and zinc pigments and salts, 1940–41

	1940		1941 (Jan.-Sept.)	
	Imports	Exports	Imports	Exports

1940	273	45		(1)	19	245	54,923
1941 (Jan.-Sept.)	107	11	(1)	1		78	19,163

[1] Less than 1 ton.

Shipments of zinc pigments from the United States, like those of the lead group, were larger during the first 9 months of 1941 than in all of 1940. Lithopone continued to be the feature of the export trade in lead and zinc pigments; it was the largest single item in both quantity and value and established a new high record. Exports of zinc oxide in the first 9 months of 1941 were larger than in any calendar year since 1930.

Details covering exports in 1941, by countries, can be shown for the first 3 months only, and these are not sufficiently complete to be recorded separately here. As indicated by tables in the preceding chapter of this series, Canada normally receives the preponderant share of exports of lithopone, 55 percent of the total for the period 1936–40 having gone to that country. South American countries have taken increasing quantities of lithopone in recent years: they took 22 percent of the total in 1940. The pattern of exports of zinc oxide differs from lithopone in that the quantities shipped do not go so largely to only a few destinations. Canada is the destination of the largest part of the zinc oxide exported, having received 37 percent of the total for 1936–40. A relatively large tonnage has gone to Asiatic countries in recent years, and increasing quantities have gone to Mexico and Brazil.

Zinc pigments and salts [1] exported from the United States, 1937–41

Year	Short tons		Total value	Year	Short tons		Total value
	Zinc oxide	Lithopone			Zinc oxide	Lithopone

GOLD, SILVER, COPPER, AND LEAD IN ALASKA

(MINE REPORT)

By Chas. W. Henderson and A. J. Martin

SUMMARY OUTLINE

SUMMARY

Gold recovered from Alaska ores and gravels in 1941 totaled 695,467 fine ounces valued at $24,341,345—a decrease of 8 percent from the 755,970 ounces valued at $26,458,950 in 1940. The value of the gold in 1941 was 99 percent of the total gross value of the gold, silver, copper, and lead produced. The silver, lead, and most of the copper produced were byproducts of gold mining. The number of producing lode mines decreased from 73 in 1940 to 56 in 1941, floating connected-bucket dredges from 49 to 47, and other types of placer operations from 1,020 to 752.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052
1940	35.00	[6] .711+	.113	.050	.063
1941	35.00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.

[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938-41 Treasury buying price for newly mined silver.

[3] Yearly average weighted price of all grades of primary metal sold by producers

[4] $0.64646464.

[5] $0.67878787.

[6] 0.71111111.

The following tables show the mine production of gold, silver, copper, and lead in Alaska in 1937–41 and 1880–1941 in terms of recovered metals; the output of gold and silver in 1941, by types of operation; and the output of gold, silver, copper, and lead from amalgamation and cyanidation mills (with or without concentration equipment) in 1941, by regions.

Gold.—Floating connected-bucket dredges recovered 44 percent of the total Alaska output of gold in 1941 compared with 47 percent in 1940. The United States Smelting, Refining & Mining Co., operating eight dredges at Fairbanks and four at Nome, was the largest producer of gold from this source in the Territory in both years. Placer mines worked by dragline and dry-land dredges, bulldozers and hydraulic giants, drifting, and sluicing together yielded 27 percent of the total gold in 1941 and 25 percent in 1940. A large part of the output from these types of operations came from the Circle, Fairbanks, Hot Springs, Iditarod (Flat), and Innoko (Folger, Ophir) districts. Lode mines contributed 29 percent of the total Alaska output of gold in 1941 and 28 percent in 1940. The Alaska Juneau Gold Mining Co. at Juneau continued to be much the largest producer of lode gold in Alaska. The Southeastern Alaska and Cook Inlet-Susitna regions yielded 88 percent of the total Alaska output of lode gold in 1941.

Silver.—All the silver produced in Alaska in 1941 was a byproduct of gold mining.

Copper.—The output of recoverable copper in Alaska in 1941 was only 144,000 pounds, of which 123,124 pounds were derived from gold ore and 20,876 pounds from copper ore.

Lead.—The bulk of the recovered lead output of Alaska in 1941 came from lead concentrates produced at the flotation mill of the Alaska Juneau Gold Mining Co.

MARKETS AND METALLURGY

About 94 percent of the gold and 52 percent of the silver produced from Alaska ores and gravels in 1941 were obtained in the form of gold-silver bullion, which was sold finally to the Seattle Assay Office and the San Francisco Mint. As there are no smelters or refineries in Alaska, all the remaining gold and silver produced and all the lead and copper were obtained from high-grade ore and concentrates shipped to smelters and refineries in the States, largely to the Tacoma (Wash.) and Selby (Calif.) smelters.

Banks and bullion buyers throughout the Territory and in Seattle, Wash., handled approximately 235,000 fine ounces of gold and 24,000 fine ounces of silver. The gold-silver bullion was either sent direct to the mints or cast into bars for shipping; in many instances the banks acted merely as agents for the lode and placer operations. The seven largest purchasers (or agents) of bullion (handling altogether over 229,000 fine ounces of gold) were: The Bank of Alaska, Anchorage; the Bank of Fairbanks and the First National Bank of Fairbanks, Fairbanks; the First National Bank of Valdez, Valdez; the Miners and Merchants Bank of Alaska, Nome; the Miners and Merchants Bank of Iditarod, Flat; and the Northern Commercial Co., Seattle, Wash.

Ore-reduction mills active in Alaska in 1941 included the 12,000-ton Alaska Juneau amalgamation-table concentration-flotation mill and about 45 other mills (chiefly amalgamation or cyanidation mills, with supplementary concentrating equipment) with reported daily capacities ranging from 2 to 72 tons. Most of the lead concentrates produced in 1941 were obtained by flotation of the dry gold ore of the Alaska Juneau Gold Mining Co. property at Juneau. Only 21 tons of copper concentrates were shipped during the year, and the small copper output of Alaska was derived mostly from gold ores. The concentrates shipped from straight concentration mills (1,720 tons) averaged 2.72 ounces of gold and 6.01 ounces of silver to the ton; those from amalgamation or cyanidation mills having concentrating equipment (3,963 tons) averaged 8 44 ounces of gold and 20.61 ounces of silver to the ton. The crude smelting ore shipped (76 tons) averaged 2.95 ounces of gold and 1.49 ounces of silver to the ton. Mill heads averaging more than 1 ounce of gold to the ton were not uncommon.

At the suggestion of miners, the United States Assay Office of the Treasury Department at Seattle, Wash., recommended that the districts in Alaska be redefined. In August and September 1941 the Denver Office of the Bureau of Mines, United States Department of the Interior, put the recommendation into effect in preparation for its 1941 canvass, and the preceding table and the "Review by regions" in this chapter follow the revised scheme. The Seattle Assay Office could not utilize the new districting during 1941, but in 1942 all receipts at that office will be listed in accordance with it.

Bullion of Alaska origin deposited at United States Assay Office, Seattle, Wash., during year ended December 31, 1941, in fine ounces

District	Gold	Silver	District	Gold	Silver
Circle	16, 497	1, 651	Kuskokwim	27, 323	1, 282
Cook Inlet	49, 457	1, 762	Nome	133, 034	11, 829
Copper River	7, 322	185	Southeastern Alaska	106, 180	22, 070
Eagle	3, 252	459	Tanana [1]	207, 740	28, 640
Iditarod	73, 652	4, 263			
Koyukuk	5, 956	583		630, 413	72, 724

[1] Includes mainly Bonnifield, Fairbanks, Hot Springs, Kantishna, and Tolovana districts in the Yukon Basin region.

REVIEW BY REGIONS

Cook Inlet-Susitna region.—This region, which includes the Iliamna, Valdez Creek, Willow Creek, and Yentna-Cache Creek districts, produced 24 percent of the total gold output from lode mines

in Alaska in 1941. There were 10 producing lode mines compared with 17 in 1940, and the output of gold decreased slightly.

The Alaska-Pacific Consolidated Mining Co., operating the Independence and Free Gold mines on the west branch of Fishhook Creek in the Willow Creek district, continued to be the largest producer of gold in the Cook Inlet-Susitna region and the second-largest producer of lode gold in Alaska. The mine is equipped with a 72-ton amalgamation-flotation mill, which was operated at capacity 7 days a week throughout the year. The ore treated averaged 1.29 ounces of gold and 0.07 ounce of silver to the ton. Mine development work resulted in 500 feet of shaft, 1,000 feet of drifts, 2,000 feet of tunnel, and 2,500 feet of diamond drilling.

The Willow Creek Mines Co., second-largest producer of gold in the Cook Inlet-Susitna region in 1941, maintained a steady output from its Lucky Shot mine and 60-ton amalgamation-flotation-cyanidation mill. The mine is on Cragie Creek approximately 1½ miles above the junction of Cragie Creek and Willow Creek and is connected with the mill by a ¼-mile aerial tram. Less gold-silver bullion and concentrates were shipped than in 1940. In treatment the ore is crushed and sent to a closed circuit, consisting of a ball mill, rake classifiers, and gold jigs. The jig concentrates are amalgamated. The classifier overflow passes into the flotation cells. The flotation concentrate goes to a regrind circuit (where more gold is amalgamated) and is then thickened, sacked, and shipped to the Tacoma (Wash.) smelter. The tails from the flotation cells are either sent to the cyanide plant or discharged into the creek.

Other leading lode-gold producers in the Cook Inlet-Susitna region were the Fern Gold Leasing Co. (operating the Fern, Goodel, and Talkeetna groups), the Gold Cord Development Co., Golden Zone Mine, Inc., and Mabelle Mines, Inc.

Placer operations, using principally hydraulic giants, recovered considerable gold from stream and bench gravels. Among the larger placer-gold producers were John E. Carlson and the White Creek Mining Co. in the Valdez district; and the Alaska Exploration & Mining Co., Cache Creek Mining Co., Devault, Devault & Seitz, Falls Creek Mining Co., Spokane Peters Creek Mining Co., and F. R. Wagner in the Yentna-Cache Creek district.

Copper River region.—The Copper River region includes the Chistochina, Nelchina, Nizina, Prince William Sound, and Yakataga (including Icy Bay) districts. The Cliff mine on Valdez Bay 10 miles west of Valdez, operated by Cliff Goldmines, Inc., was the principal producer of gold in the region in 1941. The mine is equipped with a 24-ton stamp amalgamation-gravity concentration mill which was operated 320 days and treated 2,500 tons of ore. The yield was 4,249 ounces of bullion containing 3,378 fine ounces of gold and 692 fine ounces of silver, and 36 tons of concentrates containing 81 ounces of gold and 21 ounces of silver. A plant for re-treating tailings by regrinding and flotation was nearly completed during the year. Other producers of lode gold included Yellow Band Gold Mines, Inc., in the Nizina district and the Sun Ray Mining Co. in the Prince William Sound district.

Placer gravels were worked, chiefly by hydraulicking and ground sluicing, in the Copper River region in 1941. Substantial producers of placer gold included J. M. Elmer on the Slate Creek Mining Co.

property and Einer Johnson on the Grubstake placer, both in the Chistochina district; Belanger, Cameron & Gallivan on Albert Creek in the Nelchina district; and Chititu Mines on the Rex Gulch property and Joshua Green Associates on Nicolai Placer Mines property in the Nizina district.

Kenai Peninsula region.—The Kenai Peninsula region includes the Moose Pass-Hope, Nuka Bay-Homer, and Turnagain Arm-Girdwood districts. No large producing lode or placer mines operated in this region in 1941. Most of the output of lode gold came from the Alaska Oracle Extension, East Point, and Gilpatrick mines in the Moose Pass-Hope district; the Paystreak mine in the Nuka Bay-Homer district; and the Crow Creek Gold Corporation property in the Turnagain Arm-Girdwood district. Among the producing placers were the Hope Mining Co. and Palmer Creek Mining Co. properties on Resurrection Creek in the Moose Pass-Hope district.

Kodiak Island region—Small quantities of gold were recovered by individuals from beach placering in 1941.

Kuskokwim region.—The Kuskokwim region includes the Bethel, Goodnews Bay, McGrath, and Tuluksak-Aniak mining districts. The only producing lode mine in the region in 1941 was the Nixon Fork in the McGrath district, owned and operated by Mespelt & Co.

Placers were worked in all the districts. Two floating connected-bucket dredges were operated in the Goodnews Bay district and two in the Tuluksak-Aniak district. Those in the Tuluksak-Aniak district were operated by the New York Alaska Gold Dredging Co., largest gold producer in the region in both 1941 and 1940. In the Goodnews Bay district the Bristol Bay Mining Co. operated its floating connected-bucket dredge (equipped with sixty-four 2½-cubic foot buckets) from May 9 to October 10, 1941, on Wattamuse, Slate, Culver, and Bear Creeks northerly from Goodnews Bay. The Goodnews Bay Mining Co. operated its dredge (equipped with ninety-two 8-cubic foot buckets) on Salmon River from April 26 to November 5. The company produced gold also from other ground on Salmon River and Platinum Creek and in Snow Gulch on the Arolic River, using 3-inch hydraulic giants, bulldozers, and draglines.

Among the other larger producers from dragline land dredge operations were Strandberg & Sons on Candle Creek in the McGrath district; the Marvel Creek Mining Co., Garrison Co., and Peandore Placer Mining Co. in the Tuluksak-Aniak district; John B. Huff on Butte Creek in the Arolic River area (hydraulicking); and the Eek River Mining Co. in the Bethel district.

Northwestern Alaska region.—Mining in the Northwestern Alaska region—comprising the Kiana and Shungnak districts and covering the area of the Kobuk River Valley—was confined mostly to small placer operations in 1941. The Lammers Exploration Co. shipped sizable lots of gold dust from its placer on California Creek (Shungnak district) to the Miners and Merchants Bank of Alaska at Nome.

Seward Peninsula region.—The Seward Peninsula region—comprising the Council-Bluff, Fairhaven, Kougarok, Koyuk, Nome, Port Clarence, and Serpentine River districts—had 22 floating connected-bucket dredges in 1941 (same number as in 1940); numerous bulldozer-hydraulicking, dragline land dredging, drift mining, and ground-sluicing operations; and only 1 small producing lode mine (the McDuffee, in the Nome district). Gold recovered by dredges increased 6 percent

over 1940. The average value of the gravel worked by dredges was about 47 cents per cubic yard compared with 50 cents in 1940. Most of the dredge operations in 1941 began in the period from May 10 to June 18 and ended in that from October 9 to November 23. Preparation of dredging ground is started well ahead of actual dredging, and in some places preparation of ground and general repair work are carried on throughout the year. Other types of placer operations averaged about 120 days for mines mechanically equipped.

The United States Smelting, Refining & Mining Co., in the Nome district, was the largest producer of gold in the region. The company operated three electrically powered Yuba dredges (one with 112, one with 103, and one with 78 9-cubic foot buckets) throughout the open season and in October completed and placed in operation a Yuba dredge equipped with 134 9-cubic foot buckets. Gravel washed in 1941 totaled approximately 4,000,000 cubic yards compared with 3,700,000 in 1940. The Thirty-sixth Annual Report of the United States Smelting, Refining & Mining Co. for the year ended December 31, 1941 (dated March 19, 1942), says—

> At Nome, Alaska, three dredges operated throughout the normal season and the new deep-digging dredge referred to in last year's report was started in October. In all, the four dredges operated 593 dredge days in 1941 as against 567 dredge days in 1940. Both yardage and grade were better.

Arctic Circle Exploration, Inc., operated two dredges, each with seventy 4-cubic foot buckets, on Candle Creek in the Fairhaven district and ranked second in production of gold in the region in 1941.

Castleton & Keenan, operating a Washington Iron Works Diesel-powered dredge equipped with eighty-five 2¼-cubic foot buckets on the Kougarok River in the Kougarok district, began dredging June 18 and ceased October 10. The company also operated five hydraulic giants, three caterpillar bulldozers, and a dragline and washing plant on the Kougarok River.

Lee Bros. Dredging Co. operated two Diesel-powered floating connected-bucket dredges (one with 74 and one with 66 buckets) on the Solomon River in the Nome district from June to the middle of November and handled 750,000 cubic yards of gravel.

Other companies operating floating connected-bucket dredges in the Seward Peninsula region were: The Alaska Placer Co., Camp Creek Dredging Co., Council Dredging Co., Inland Dredging Co., and Ophir Gold Dredging Co., all in the Council-Bluff district; Dry Creek Dredging Co. and Forsgren Dredging Co., both operating on the Inmachuk River in the Fairhaven district; Fox Bar Dredging Co. in the Kougarok district; Ungalik Syndicate in the Koyuk district; and American Creek Dredging Co., Casa de Paga Gold Co., Osborn Creek Dredging Co., and Tolbert Scott, all in the Nome district.

Among the large producers of gold from placers worked by hydraulic giants, with some combination of bulldozers, draglines, and pumping equipment in addition, were: Crabtree & Sullivan in the Council-Bluff district; Wallace Porter in the Fairhaven district; The Alaska Taylor Mining Co., Carlson & Co., Dahl Creek Mining Co., Gold Bullion, Inc., Grant Mining Co., Rainbow Mines, Trinity Mining Co., George Waldhelm, and Wirum Bros., all in the Kougarok district; Gabe Johnson & Co., Gold Beach Placers, Margraf & Kowalski, E. W. Quigley, and C. O. Roberts, all in the Nome district; and Gilbert Fidjeland and Frank L. Rice, both in the Port Clarence district.

Southeastern Alaska region.—Southeastern Alaska—including the Admiralty Island, Chichagof Island, Hyder, Juneau, Ketchikan, and Windham Bay districts—produced 64 percent of the total lode gold and most of the silver, copper, and lead output of Alaska as a whole in 1941. There were 16 active mines—7 less than in 1940.

The Alaska Juneau was the largest producer of silver and lead and was second only to the United States Smelting, Refining & Mining Co. in output of gold in the Territory in 1941. The Twenty-seventh Annual Report of the Alaska Juneau Gold Mining Co. for the year ended December 31, 1941 (dated March 14, 1942), says—

During 1941 the amount of rock trammed from the mine was 4,354,770 tons. Compared to the previous year's production, this represents a decrease of slightly over 1,000 tons per day. The North ore body furnished 15 percent of the year's tonnage, the South ore body 38 percent, while the Perseverance section of the mine supplied 47 percent of the total.

During the year, 333,250 pounds of powder were used in blasting powder drifts; 33,750 pounds were used in blasting long hole stations, making a total of 367,000 pounds of powder for primary breaking, or 0.08 pound per ton trammed. Total powder consumption for primary and secondary breaking was 0.29 pound per ton trammed in 1941, as against 0.32 pound in 1940, and 0.32 pound in 1939. This gives a tonnage ratio of 3.45 tons of rock per pound of powder used for 1941, as against 3.13 tons in 1940.

In the Deep North ore body, work was started on ore pockets, skip loading apparatus, stations, and tipple installations in and around the Main shaft on 13 level, which is 1,450 feet below the collar of the winze. Work on the tipples and tunnel widening is still in progress but should be finished within a few months. Additional exploratory work was done in the western part of the Deep North ore body, while in the 91 winze area, ore-way raise work is still in progress.

While exploratory, development, and preparatory mining work was carried on throughout the year, the rate at which it was being done during the second half of the year was below the normal requirement. Any such prolonged curtailment of development and preparatory mining will directly affect future tonnage output, although the effect may be delayed somewhat, inasmuch as it generally takes about two years to bring a stope into production. This reduction of preparatory mining work is due to the shortage of labor and to the high turn-over of labor, both being results of the present national emergency.

Mill.—There were no alterations to the mill flow sheet during the year. The only additional equipment installed was a small Oliver filter, which handles a mixture of flotation and table concentrates.

Power plants.—The relocation of part of the Annex Creek electric transmission line was completed during the summer of 1941. The repair work at Salmon Creek Dam was continued, but due to labor shortage it was not completed.

Labor.—All during the year, except for the first 4 months, there was a very marked shortage of both skilled and unskilled labor in all departments. During the last few months of the year, we operated with 200 less men daily than during the previous year. Labor turn-over reached the highest point in the history of the mine. The average monthly percentage turn-over during the last 6 months was 10 percent, which is about three times greater than the normal turn-over.

In May 1941 a wage increase of about 7 percent was granted and a Union shop agreement was entered into with the Juneau Mine and Mill Workers Union affiliated with International Mine, Mill and Smelter Workers Union.

The average wage per day was $7.17 in 1941 as compared to $6.69 in 1940. The number of men employed at the end of the year was 866.

The over-all cost per man per day was $11.14 in 1941, as compared to $10.87 in 1940.

Gold content of ore from Alaska Juneau mine, 1937–41, and total, 1893–1941

Year	Rock to mill from mine (tons)		Gold (ounce)				
			Recovery per ton fine-milled		Losses per ton of tailings		Content of rock from mine to mill
	Ore fine-milled	Coarse tailings rejected	In bullion	In galena concentrates	Fine	Coarse

Profit before depreciation, depletion, and income taxes	1,202,964.46		1,165,079 77		21,673,181 26	

The Hirst-Chichagof Mining Co. on Chichagof Island operated its mine and 35-ton amalgamation-flotation mill continuously in 1941 and was again the second-largest producer of gold in the region. The bullion product was sent direct to the Seattle Assay Office, and the concentrates were shipped to the Tacoma (Wash.) smelter.

The Chichagof Mining Co. at Klag Bay in the Chichagof Island district continued to treat old tailings, producing gold-silver concentrates (containing a little copper) which were shipped to the Tacoma (Wash.) smelter.

The output from other mines in the region was small. Companies or individuals producing more than 100 ounces of gold from lode mines were the Alaska Empire Gold Mining Co. in the Admiralty Island district, the LeRoy Mining Co. in the Juneau district, and Wendell Dawson in the Ketchikan district. Small sluicing operations in the Juneau and Windham Bay districts recovered placer gold.

Yukon River Basin region.—The Yukon River Basin region includes the following mining districts: Bonnifield-Nenana, Chandalar, Chisana, Circle, Delta River, Eagle, Fairbanks, Fortymile, Goodpaster, Hot Springs, Hughes, Iditarod, Innoko, Kantishna, Koyukuk, Marshall, Rampart, Ruby, Tolovana, and Yukon Flats. The region yielded 59 percent of the total output from connected-bucket dredges in Alaska during 1941; it ranked first in gold recovered from other placers and third in that from lode mines.

Twenty-two floating connected-bucket dredges (including one single-dipper dredge) were operating in the region—two less than in 1940.

The United States Smelting, Refining & Mining Co., operating eight floating connected-bucket dredges in the Fairbanks district, was much the largest producer of gold and silver in the Yukon River Basin region. The company operated two 10-cubic foot Bethlehem dredges (with 111 and 93 buckets, respectively), one 10-cubic foot Yuba dredge (with 106 buckets), three 6-cubic foot Bethlehem dredges (with 78, 78, and 68 buckets, respectively), one 5-cubic foot Yuba dredge (with 84 buckets), and one 3-cubic foot Yuba dredge (with 68 buckets); all the dredges are electrically operated. Other equipment used (chiefly for removing overburden) included 365 Joshua Hendy hydraulic giants, one 8- to 12-cubic yard electric-powered Bucyrus 10-W dragline, and one oil-burning caterpillar bulldozer. Of the dredges operated in 1941, two were on Cleary Creek, two on Goldstream Creek, and one each on Cripple, Ester, Fish, and Pedro Creeks.

The Thirty-sixth Annual Report of the United States Smelting, Refining & Mining Co. for the year ended December 31, 1941 (dated March 19, 1942), says—

At Fairbanks, Alaska, the gold output for the season was considerably lower than in 1940. This was due to a strike which lasted from June 6 to July 2, 1941, shutting down all operations and resulting in a loss of 216 dredge days for the eight dredges; and to decrease in the output of the new large dredge, which spent most of the season of 1941 digging in tailings and lower-grade gravels. In all, the dredges operated 1,611 dredge days in 1941 as against 1,799 dredge days in 1940.

At both Fairbanks and Nome there were further acquisitions of ground in 1941. Continued development resulted in gold-reserve additions which considerably exceeded the year's extraction.

In the Circle district three dredges were again active in 1941. Alluvial Golds, Inc., operated its W. W. Johnson Co. dredge (with

seventy-two 4-cubic foot buckets) on Woodchopper Creek. On Coal Creek, Gold Placers, Inc., ran a dredge of similar type equipped with sixty 4-cubic foot buckets. The C. J. Berry Dredging Co. operated its steampowered dredge (with fifty-eight 3-cubic foot buckets) and handled about 318,200 cubic yards of gravel. The output by these three dredges ranked the Circle district second in gold produced by dredges in the Yukon River Basin in 1941.

The Tolovana district, with two dredges, ranked third in the region in gold produced by dredges. Livengood Placers, Inc., made a large output from its Yuba dredge on Livengood Creek, equipped with eighty-eight 6-cubic foot buckets. The Nome Creek Mining Co. operated a W. W. Johnson Co. dredge (with 4-cubic foot buckets) on Nome Creek northeast of Fairbanks.

In the Iditarod district the North American Dredging Co. operated a Washington Iron Works dredge (with sixty-nine 3-cubic foot buckets) on Otter Creek from May 19 to November 5. The Riley Investment Co. also operated a dredge on Otter Creek.

Three dredges were active in the Innoko district in 1941; the Ganes Creek Dredging Co. and Moss & Larson operated one each on Ganes Creek, and Nels J. Vibe ran one on Yankee Creek.

In the Fortymile district the Boundary Dredging Co. operated a W. W. Johnson Co. 60-bucket dredge on Canyon Creek from July 22 to October 12. On Wade Creek the Wade Creek Dredging Co. continued to operate its Risdon steam-powered dredge equipped with seventy 3½-cubic foot buckets.

In the Bonnifield-Nenana district Standard Mines, Inc., operated a Becker-Hopkins single-bucket floating dredge on Eva Creek. The bucket is mounted on a steel framework at the digging end of the dredge in such a manner as to permit it to be elevated to an angle that allows the gold-bearing gravel to be discharged into a trommel screen on the floating washing plant. The washing plant and stacker unit are similar to those on lightweight connected-bucket dredges.

On Caribou Creek in the Delta River district the Brinker-Johnson Co. operated its W. W. Johnson Co. dredge, equipped with seventy-eight 4½-cubic foot buckets, from June 15 to November 7, 1941.

Placer operations of all types—other than floating connected-bucket dredges—were to be found throughout the Yukon River Basin region, some with production as large as or larger than the average dredge and many producing over 500 ounces of gold. The combined production of these operations was at least 100,000 fine ounces of gold in 1941.

In the Bonnifield-Nenana district Triple X Placers operated a 1½-cubic yard Bucyrus dragline, an Isaacson washing plant, and two caterpillar bulldozers on the Totatlanika River from June 1 to September 25 and handled 200,000 cubic yards of gravel.

Among the larger producers in the Circle district using hydraulic giants and bulldozers or draglines with screening and sluicing plants were: The Berry Holding Co., Bergstrom & Savage, Central Mining Co., Frank & Co., Independence Mining Co., F. B. Johnston Mining Co., Jack LaCross, and Mastodon Mining Co.

In the Fairbanks district Helmer Johnson handled approximately 35,000 cubic yards of gravel with hydraulic giants and a bulldozer at his placer on upper Cleary Creek; the yield was 1,157 fine ounces of gold and 190 fine ounces of silver. The Wolf Creek Mining Co.,

operating a dragline and washing plant on Wolf Creek, continued to be an important producer of gold. The Fish Creek Mining Co. on upper Fish Creek and the Faith Creek Mining Co. on Faith Creek (tributary to Chatanika River) recovered substantial quantities of gold by hydraulicking, bulldozing, and sluicing. The First Chance Mining Co. worked its claim in First Chance Creek 14 miles from Fairbanks from March 25 to October 10, using six hydraulic giants, a Diesel-powered 1-cubic yard dragline, and a bulldozer; the gravel handled (100,000 cubic yards) had an average value of 15 cents a cubic yard, based upon net returns from the gold and silver sold. Other sizable producers in the Fairbanks district included the Alder Creek Mining Co., Brown & Reeves, the Gilmore Mining Co., O. M. Grant, Robert O. Jones, and J. H. Martin.

In the Fortymile district the Central Development Syndicate continued to be an important producer of gold from company owned and leased ground on Jack Wade Creek; hydraulic giants and bulldozers were used to handle the gravel.

Among the larger placer operators in the Hot Springs district were the Cleary Hill Mines Co., operating 12 hydraulic giants, 1 dragline, and 2 bulldozers on Sullivan Creek; J. R. Frank & Co. and Whitehead & Co., hydraulicking on Pioneer Creek; and the Montana Mining Co., using hydraulic giants with a dragline and bulldozer on Omega Creek.

On Utopia Creek (tributary to Indian River) in the Hughes district L. McGee handled 200,000 cubic yards of gravel, using four hydraulic giants, two bulldozers, and a dragline in conjunction with a land washing plant; the average value of the gravel was 43.5 cents a cubic yard. McGee also worked ground on Black Creek and Indian River with hydraulic giants and bulldozers; the gravel washed (45,000 cubic yards) had an average value of 51.3 cents a cubic yard.

In the Iditarod district the larger producers from these types of placer operations were: The Awe Mining Co., the Granite Mining Co., Hatten, Bauquier & Turner, Sakow & Tomoff, Turner & Remington, and Uotila & Ogriz.

In the Innoko district Three Miners, Inc., operated its dragline and portable dry-land washing plant on the Innoko River about 30 miles northwest of Ophir from March 15 to September 30, 1941. Degnan & Rosander and the Cripple Creek Mining Co operated similar equipment on Little Creek and Cripple Creek, respectively. Hard, Uotila & Hansen operated seven hydraulic giants, a 1½-cubic yard dragline, and a bulldozer on Bear Creek from April to October. Other large placer operators were Beaton & McDougall, Peter Miscovich & Sons, the Moore Creek Mining Co., Sid Paulson, and Savage & Matheson.

On Caribou Creek in the Kantishna district Caribou Mines handled 119,668 cubic yards of gravel from June 20 to September 16, using a 1½-cubic yard dragline, two bulldozers, and a dry-land washing plant, all of which used oil for fuel

The principal producer of gold in the Koyukuk district in 1941 was Repo & Schwaesdall, who operated hydraulic giants, bulldozers, and a dragline on Myrtle Creek.

In the Marshall district the Wilson Creek Mining Co operated its dragline and two bulldozers in conjunction with elevated sluices on Elephant Creek (tributary to Wilson Creek) from April 21 to October 21 and handled 235,888 cubic yards of gravel having an average value

of 25.6 cents a cubic yard. The Yukon Mining Co. mined from June 18 to October 11 on placer ground on Buster and Windy Creeks; sluicing was done on bedrock, and a dragline was used to stack the tailings. H. Roy Hunter operated two hydraulic giants, a dragline, and two bulldozers from June 1 to October 15 on Willow Creek 12 miles southeast of Fortuna Ledge

Other large producers among these types of placer operations in the Yukon River Basin region in 1941 were the Long Creek Mining Co and Richardson & Johnson in the Ruby district, and Parker & Son and A. W. Warwick in the Tolovana district.

Lode mining in the Yukon River Basin region produced 16,763 fine ounces of gold and 8,114 fine ounces of silver in 1941, decreases of 17 percent in gold and 5 percent in silver from 1940.

The leading producer of lode gold in the region in 1941 was Cleary Hill Mines, Inc., operating the Cleary Hill mine and amalgamation-flotation mill in the Fairbanks district 27 miles northeast of Fairbanks. The United States Smelting, Refining & Mining Co. operated its McCarty mine on Fairbanks Creek continuously in 1941, except during a strike which lasted nearly a month; the mine is equipped with a 10-ton amalgamation mill. The Hi Yu Mining Co. continued small-scale mining at its Hi Yu mine on Fairbanks Creek; the ore was treated in the 50-ton amalgamation mill on the property. Other small lode-gold producers in the Fairbanks district included the Carver Alder Mine Co., Emma Creek Mine Co. (a partnership), O. M. Grant, Lloyd Lounsberry, and the Tolovana Mining & Milling Co.

In the Kantishna district the Red Top Mining Co. operated its Red Top mine and 50-ton jig-, table-, and flotation-concentration mill from March 3 to October 26; the jig and table concentrates are amalgamated in a barrel, and the barrel tails and the flotation concentrates are shipped to the Tacoma (Wash.) smelter.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN ARIZONA

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

SUMMARY

The total value of the output of recoverable metals from mines in Arizona was $97,638,310 in 1941 compared with $82,167,759 in 1940—an increase of 19 percent (see fig. 1); it was the greatest since 1929, when the total value was $155,567,133. Both quantity and value of each of the five metals increased substantially in 1941. The total value of the gold was $11,038,720, a 7-percent gain over 1940; silver $5,332,096, a 6-percent gain; copper $77,010,812, a 21-percent gain; lead $1,782,732, a 34-percent gain; and zinc $2,473,950, a 27-percent gain. The value of the gold production represented 11 percent of the State total, silver 5 percent, copper 79 percent, lead 2 percent, and zinc nearly 3 percent. The total value of the metals recovered from copper ore was $84,957,995 in 1941, or 87 percent of the State total. The output of copper in 1941 was the greatest since 1929, and the outputs of both lead and zinc were the largest in the history of the State. The output of placer gold (11,931 fine ounces) was larger than in any year since records were established in 1901 and resulted chiefly from the operation of two dragline-floating dredges in Yavapai County.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.101	.047	.052
1940	35.00	[6] .711+	.113	.050	.063
1941	35.00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+ ($20.671835) per fine ounce.

[2] 1937. Yearly average weighted Treasury buying price for newly mined silver, 1938–41. Treasury buying price for newly mined silver.

[3] Yearly average weighted price of all grades of primary metal sold by producers.

[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Arizona, 1937–41, and total, 1860–1941, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)

[1] Includes placer sands treated by dry concentration plants
[2] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge "
[3] Figures for dragline floating dredges include those for dry-land dredges

Gold.—The output of recoverable gold in Arizona in 1941 was 315,392 fine ounces—an increase of 7 percent over 1940. Gold from siliceous ores (chiefly dry and siliceous gold ore) and zinc-lead ore was virtually the same as in 1940, but gold from copper ore increased 13,778 ounces and that from lead ore 1,234 ounces. Gold from placers increased 5,690 ounces; 84 percent of the total placer gold was recovered by dragline dredging at properties on Big Bug Creek and Lynx Creek in Yavapai County. The Copper Queen (Bisbee) branch of the Phelps Dodge Corporation continued to be the leading gold producer in Arizona; it was followed by the New Cornelia mine in Pima County, the Mammoth-St. Anthony Limited property in Pinal County, the Goldroad mine (United States Smelting, Refining

& Mining Co.) in Mohave County, and the United Verde mine in Yavapai County; these five properties produced more than 58 percent of the State total output. Other large gold producers were the Magma mine in Pinal County, the Octave mine (American Smelting & Refining Co.) in Yavapai County, the Shattuck Denn mine in Cochise County, the Iron King mine in Yavapai County, the Tyro mine (Gold Standard Mines Corporation) in Mohave County, and the

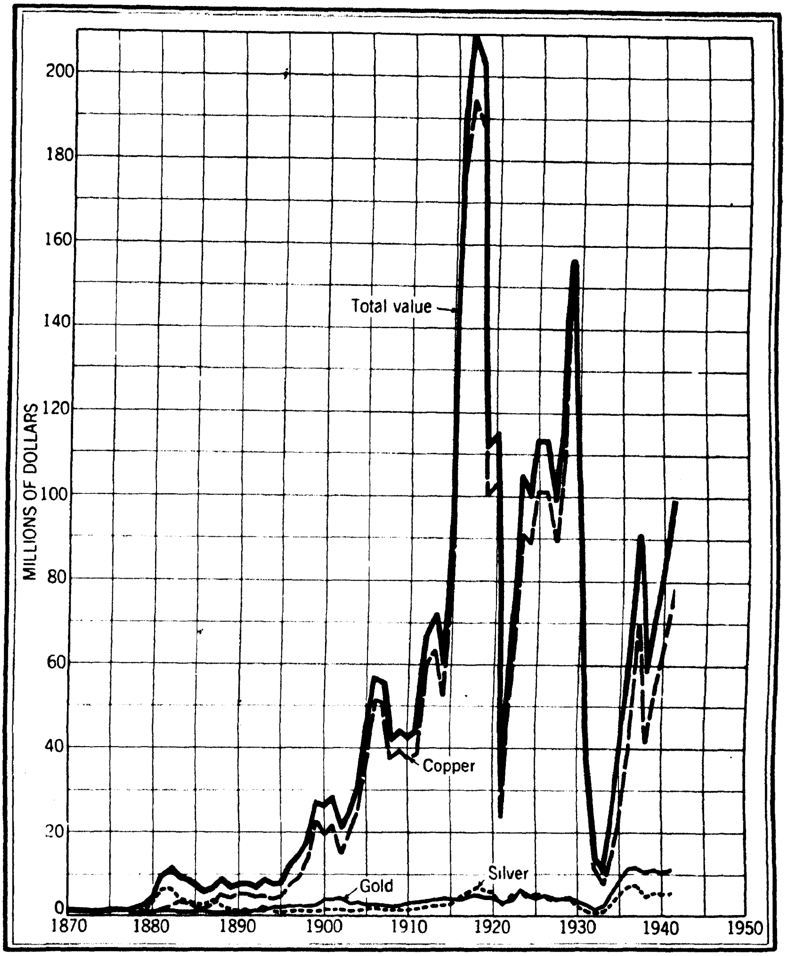

FIGURE 1.—Value of mine production of gold, silver, and copper and total value of gold, silver, copper, lead, and zinc in Arizona, 1870–1941. The value of lead and zinc has been less than $2,000,000 annually, except in a few years.

Congress property in Yavapai County. Siliceous ores yielded 46 percent of the State total gold, copper ore 45 percent, and zinc-lead ore 4 percent. The chief gold-producing districts in Arizona were the Warren (mostly copper ore), San Francisco (nearly all gold ore), Ajo (copper ore), Verde (mostly copper ore), Old Hat (nearly all gold ore), Weaver (Yavapai County) (gold ore), and Big Bug (mostly zinc-lead ore and placer gold).

Silver.—The output of recoverable silver in Arizona in 1941 was 7,498,260 fine ounces—an increase of 6 percent over 1940. Silver from siliceous ores declined 182,504 ounces and that from zinc-lead ore 48,992 ounces; but silver from copper ore increased 542,672 ounces, that from lead ore 62,609 ounces, and that from zinc-copper ore 32,600 ounces. Copper ore yielded 67 percent of the State total silver, siliceous ores 16 percent, zinc-lead ore 12 percent, zinc-copper ore 3 percent, and lead ore nearly 2 percent. The Phelps Dodge Corporation continued to be the chief silver producer in Arizona, and its output was 17 percent greater than in 1940; its four properties (Copper Queen, Morenci, New Cornelia, and United Verde) produced 40 percent of the State gold output, 54 percent of the silver, and 53 percent of the copper. Other large silver producers in Arizona in 1941 were the Magma, Shattuck Denn, Trench-Flux, Iron King, and Iron King-Equator properties. The chief silver-producing districts were the Warren (Bisbee), Verde (Jerome), Pioneer (Superior), Ajo, Harshaw, Big Bug, and Wallapai (Chloride); more than 56 percent of the total silver came from the Warren and Verde districts.

Copper.—The output of recoverable copper in Arizona in 1941 was 652,634,000 pounds—a 16-percent gain over 1940 and the largest output since 1929, when it was 830,628,411 pounds. There was a substantial increase in each of the seven chief copper-producing districts. The Globe-Miami district, with a production of 164,837,300 net pounds of copper, continued to be the leading copper-producing area in Arizona; it was followed by the Ajo district with 131,760,000 pounds, Warren (Bisbee) with 113,184,100 pounds, Mineral Creek (Ray) with 84,800,000 pounds, Verde with 84,484,800 pounds, Pioneer (Superior) with 38,238,400 pounds, and Copper Mountain (Morenci) with 27,757,800 pounds. These seven districts contributed 99 percent of the State total copper. Copper ore and its products yielded 647,420,204 pounds of copper, as follows: 18,607,089 tons of copper ore treated by concentration yielded 58 percent; 1,760,740 tons of copper ore shipped crude to smelters, 24 percent; and 3,785,654 tons of copper ore leached and 21,373 tons of cement copper (from mine-water precipitates and underground leaching operations), 18 percent. The New Cornelia property continued to be the largest copper producer in Arizona; it was followed in order by the Copper Queen, Inspiration, Ray (Nevada Consolidated Copper Corporation), United Verde, Miami, Magma, and Morenci (Phelps Dodge Corporation).

Lead and zinc.—The output of recoverable lead in Arizona in 1941 was 31,276,000 pounds—the largest output in any year in the history of the State and an increase of 18 percent over 1940; the output of recoverable zinc was 32,986,000 pounds—also the largest in any year in the history of the State and an increase of 7 percent over the record output in 1940. About 40 percent of the State total lead and 32 percent of the zinc came from Santa Cruz County, nearly 16 percent of the lead and 14 percent of the zinc from Mohave County, and 15 percent of the lead and 25 percent of the zinc from Pinal County; nearly all the remainder of the lead and zinc came from Yavapai and Cochise Counties. About 68 percent of the total lead and 74 percent of the total zinc came from zinc-lead ore; nearly all the rest of the lead came from siliceous ores, lead ore, zinc-copper ore, and copper ore, and nearly all the rest of the zinc from zinc-copper

ore. The Trench-Flux group of the American Smelting & Refining Co. near Patagonia in Santa Cruz County was by far the largest producer of lead in the State; it was followed by the Tennessee mine at Chloride, Mammoth-St. Anthony Limited property at Tiger, Shattuck Denn mine at Bisbee, Duquesne property near Patagonia, Hillside mine near Hillside, "79" mine near Hayden Junction, and Iron King mine at Humboldt. The largest producer of zinc in the State was the Magma mine at Superior; it was followed by the Trench-Flux, Tennessee, Shattuck Denn, Iron King, Duquesne, and Hillside properties.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Arizona in 1941, by counties, in terms of recovered metals

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer	Fine ounces	Value	Fine ounces	Value
Cochise	35	2	63,441	$2,220,435	2,763,616	$1,965,238

[1] Includes placer sands treated by dry concentration plants.
[2] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

MINING INDUSTRY

The mining industry continued to improve in Arizona in 1941, as a result of the demand for copper, lead, and zinc; more ore was mined than in any year (except 1929) in the history of the State. The output of copper ore increased to 24,153,483 tons—a 19-percent gain over 1940—but the output of zinc-lead ore declined to 260,473 tons—a 4-percent loss; however, the production of both lead and zinc was the largest ever recorded in the State. A total of 23,994,259 tons (94 percent of the State total ore output) was copper ore mined in the Globe-Miami, Ajo, Mineral Creek (Ray), Verde (Jerome), Warren (Bisbee), Copper Mountain (Morenci), and Pioneer (Superior) districts; virtually all the zinc-lead ore was mined in the Big Bug, Harshaw, Wallapai (Chloride), Eureka (Hillside), Patagonia, and Warren (Bisbee) districts. The output of siliceous ores (chiefly gold ore) increased to 975,790 tons—a 5-percent gain over 1940 and lead ore to 18,432 tons—a 109-percent gain; zinc-copper ore increased slightly to 80,810 tons. Placer mining, chiefly dredging operations, was the greatest in any year since records were established in 1901.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Arizona in 1941, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	471	800, 804	130, 298	213, 360	322, 564	4, 482, 513	
Dry and siliceous gold-silver ore	68	138, 611	13, 187	526, 518	542, 414	457, 950	
Dry and siliceous silver ore	72	36, 375	713	455, 936	192, 522	49, 792	
	[1] 594	975, 790	144, 198	1, 195, 814	1, 057, 500	4, 990, 255	
Copper ore	144	24, 153, 483	142, 498	5, 006, 374	[2] 647, 420, 204	261, 278	
Lead ore	98	18, 432	2, 129	130, 985	142, 351	4, 378, 355	
Lead-copper ore	5	663	19	3, 745	22, 668	62, 280	
Zinc ore	2	2, 143	58	13, 168	13, 270	17, 700	235, 200
Zinc-copper ore	1	80, 810	1, 069	224, 400	2, 533, 700	355, 000	8, 278, 000
Zinc-lead ore	10	260, 473	13, 490	921, 569	1, 444, 307	21, 211, 132	24, 472, 800
Total, lode mines	[1] 805	25, 491, 794	303, 461	7, 496, 055	[2] 652, 634, 000	31, 276, 000	32, 986, 000
Total, placers	184		11, 931	2, 205			
	989	25, 491, 794	315, 392	7, 498, 260	[2] 652, 634, 000	31, 276, 000	32, 986, 000
Total, 1940	1, 300	21, 572, 175	294, 807	7, 075, 215	[3] 562, 338, 000	26, 532, 000	30, 912, 000

[1] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.
[2] Includes 118,450,902 pounds recovered from ore leached and mine-water precipitates.
[3] Includes 103,327,137 pounds recovered from ore leached and mine-water precipitates.

METALLURGIC INDUSTRY

Of the 25,491,794 tons of ore produced in 1941 in Arizona, 19,001,720 tons (75 percent) were treated at concentration plants, 3,785,654 tons (15 percent) were treated at a leaching plant, 833,910 tons (3 percent) were treated at amalgamation and cyanidation mills, and 1,870,510 tons (7 percent) were shipped crude to smelters.

Gold ore treated at amalgamation mills increased from 4,162 tons in 1940 to 7,517 tons in 1941 and siliceous material treated at cyanidation plants from 742,801 to 826,393 tons. Cyanidation plants were operated continuously in 1941 at the Goldroad, Gold Standard, Producers Mines, Inc., Congress, Octave, Mammoth-St. Anthony Limited, Alvarado, Yarnell, Vulture, Vivian, and Iron King properties. Nine companies reported cyaniding 667,990 tons of siliceous material and using 132,570 pounds of sodium cyanide, 1,142,000 pounds of Aero Brand calcium cyanide, 80,775 pounds of zinc dust, 2,776,950 pounds of lime, 1,175 pounds of aerosol, 200 pounds of lead acetate, and 165 pounds of lead nitrate.

Ore treated at concentration plants in 1941 comprised 6,940 tons of gold ore, 36,440 tons of gold-silver ore, 2,100 tons of silver ore, 18,607,089 tons of copper ore, 5,950 tons of lead ore, 600 tons of lead-copper ore, 2,143 tons of zinc ore, 80,810 tons of zinc-copper ore, and 259,648 tons of zinc-lead ore. Copper ore from the Miami property (5,821,077 tons) was treated by a combination of leaching and concentration and copper ore from the Inspiration mine was treated by straight leaching, but 298,706 tons of slimes discarded from the leaching-plant feed were concentrated. Large copper-concentration plants were operated continuously in 1941 at Ajo, Clarkdale, Hayden, Miami, Morenci, and Superior; copper-leaching plants at Inspiration and

Miami; and copper smelters at Clarkdale, Douglas, Hayden, Miami, and Superior. The 20-ton smelter at Tiger is the only lead smelter in Arizona, and it operated exclusively on concentrates from the mill of Mammoth-St. Anthony, Ltd.

The following tables give details of the treatment of all ores produced in Arizona in 1941.

Mine production of metals in Arizona in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated	7,517	888	297			
Ore and old tailings cyanided	826,393	77,627	182,503			
Concentrates smelted	1,028,852	114,974	2,782,173	378,843,659	26,981,425	32,693,800
Ore smelted	1,870,510	109,972	4,531,082	155,339,439	4,294,575	292,200
Copper precipitates smelted	21,373			[1] 34,323,752		
Copper ore leached	[2] 3,785,654			84,127,150		
Placer		11,931	2,205			
		315,392	7,498,260	652,634,000	31,276,000	32,986,000
Total, 1940		294,807	7,075,215	562,338,000	26,532,000	30,912,000

[1] Distributed as follows: Cochise County, 821,616 pounds; Gila County, 6,086,086 pounds; Greenlee County, 12,485,800 pounds; Pinal County, 13,800,000 pounds, and Yavapai County, 1,130,250 pounds.
[2] Treated by straight leaching at 1 plant in Gila County.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Arizona in 1941, by types of mills and by counties, in terms of recovered metals

AMALGAMATION MILLS

[1] Ellsworth district lies in both Maricopa and Yuma Counties.
[2] Old Hat district lies in both Pima and Pinal Counties.

COCHISE COUNTY

California district (Hilltop).—Lessees operated the Columbia and Hilltop mines in 1941 and shipped silver-lead ore to the smelter at El Paso, Tex.

Cochise district.—Approximately 900 tons of copper ore were produced in 1941 from the old Republic mine near Dragoon.

Dos Cabezas and Tevis district.—The Dives property, operated by the Santa Maria Mining Corporation, was the chief producer in the Dos Cabezas and Tevis district in 1941; about 700 tons of crude gold ore were shipped to a smelter. Other producers of gold ore included the Gold Prince and Gold Spot properties.

Hartford (Huachuca Mountains) district.—Nearly all the output in the Hartford district in 1941 was silver-lead ore from the Armistice group near Hereford.

Kimball (Peloncillo) district.—Small lots of copper ore were produced in 1941 from the Quien Sabe and Willie Rose claims near San Simon.

Swisshelm district (Elfrida).—The metal output of the Swisshelm district was much greater in 1941 than in 1940, owing to the marked increase in shipments of silver-lead ore from the Scribner mine; lessees shipped about 3,000 tons of ore to El Paso, Tex. Silver-lead ore was produced also from the Chance, Juan Lares, and No Name No. 1 properties.

Tombstone district.—Gold-silver ore and silver-lead ore from the Tombstone Development property continued in 1941 to be the most important output in the Tombstone district; however, production declined to 4,180 tons in 1941. The remainder of the district output was mainly silver-lead ore from the Tombstone Extension mine and silver ore from the Manganese Silver and South Bonanza properties.

Turquoise district (Courtland, Pearce, Gleeson).—About 700 tons of lead ore and 200 tons of zinc-lead ore were produced in 1941 from the Defiance mine and 333 tons of gold-silver ore from the Commonwealth mine. The rest of the district output was chiefly lead ore from the No Account group.

Warren district (Bisbee, Warren).—The value of the metal output of the Warren district in 1941 increased nearly 7 percent over 1940. Crude copper ore (1,080,969 tons) from the Copper Queen branch of the Phelps Dodge Corporation was again the principal output; the property remained the largest producer of gold and silver in the State and ranked second in copper.

The Bisbee mines of the Copper Queen branch of the Phelps Dodge Corporation produced 836,248 tons of ore from the Limestone area, according to the annual report of the corporation for 1941. Operations were conducted virtually at capacity throughout the year; shipments of siliceous flux to the Douglas smelter from the Southeast Extension porphyry ore body totaled 214,075 tons; lease operations produced 30,646 tons of copper ore; and shipments of copper precipitates from surface and underground plants aggregated 807 tons. The advance in exploration, development, and stope preparation totaled 65,238 feet; in addition, 15,824 feet of diamond drilling were done. The total footage driven for exploration and development was less than in 1940, but satisfactory results were obtained in maintaining ore reserves. At the end of August a very heavy flow of water, which flooded the mine up to the 2,433 level, was encountered east of the Campbell fault on the 2,700 level. Large sinking pumps were in-

stalled, and by the end of the year the mine had been unwatered with the exception of an area east of the Campbell fault. The flood did not interfere seriously with ore production but did retard development.

The flood extended into the Denn mine of the Shattuck Denn Mining Corporation and caused suspension of copper-ore production during September; in consequence, the output of copper ore decreased from 124,811 tons in 1940 to 102,828 tons in 1941; however, the output of zinc-lead ore from the mine increased to 20,115 tons. The remainder of the district production was mostly copper ore from the Shattuck mine and rich gold ore from the Sure Thing claim.

COCONINO COUNTY

Francis district.—The output of the Francis district in 1941 was copper ore from the Emerald & Ruby property.

Jacob Canyon and Warm Springs district.—A total of 987 tons of carbonate copper ore was produced in 1941 from the Brown Derby, Mackin, and Petoskey properties; the Mackin mine was by far the largest producer.

GILA COUNTY

Banner and Dripping Springs district.—The Sam Knight Lease operated the Christmas mine continuously in 1941 and shipped 35,791 tons of copper ore to a smelter—a substantial increase over 1940. Lead ore (2,979 tons) and zinc-lead ore (280 tons) were produced from the "79" mine and gold ore from the Apex, Columbia, Gold Queen, Round Top, and Standard properties. The rest of the district output was mainly copper ore from the Round Top and Chilito mines.

Globe-Miami district.—The Globe-Miami district, with a production of 164,837,300 net pounds of copper in 1941, remained the chief copper-producing area in Arizona; the output increased 17 percent over that in 1940. The Inspiration property, with a yield of 91,841,640 net pounds of copper, was the largest producer of copper in the district and ranked third in the State. According to the printed annual report of the Inspiration Consolidated Copper Co. for 1941, 3,843,931 tons of copper ore from which the slimes had been removed were treated by ferric sulfate leaching. The ore averaged 1.23 percent copper, of which 0.659 percent was oxide and 0.571 percent sulfide; extraction was 98.483 percent of the oxide and 80.21 percent of the sulfide. The slimes (298,706 tons) removed from the ore were treated at the concentrator to recover the sulfide copper, and the tailings were treated with sulfuric acid to dissolve the oxide copper. Leaching operations were at the highest rate since operations began in 1926. A monthly production of 8,000,000 pounds of net copper was attained in August and maintained throughout the remainder of the year. The company has contracted for the building and equipping of a new acid plant and has started the necessary alterations and new installations in the concentrator to increase the production of copper by about 2,000,000 pounds a month. The Miami Copper Co. operated its 18,000-ton concentrator and 3,000-ton leaching plant continuously and treated 5,821,077 tons of copper ore, an increase of 10 percent over 1940. According to the printed annual report of the company, it is estimated that the mining of the mixed ore body will be completed about September 1942. After this date the tonnage will be replaced by a somewhat larger tonnage of sulfide ore, which will tend to reduce copper production, as the sulfide ore yields less copper per ton than does

the mixed ore. To increase copper production beyond the existing capacity of the property, facilities were installed during the year for leaching and precipitating copper from the broken ore and capping that remaining in abandoned parts of the mine; copper production from this source was begun in January 1942. The rest of the district output was largely crude silver ore and zinc-lead ore from the Old Dominion property and crude copper ore from the Carlota mine.

Green Valley district (Payson).—Virtually all the metal output of the Green Valley district in 1941 was gold ore, mainly from the Planet, Golden Hill, and Payrock properties.

Pioneer (Pinal Mountains) district.—About 154 tons of ore were produced in the Pioneer district in 1941; most of it was silver ore from the Pioneer mine, copper ore from the Bob Tail group, and lead ore from the Penial claim.

Summit district.—A little copper ore was produced in 1941 from the Ritchard and Yan properties near Miami.

GRAHAM COUNTY

Nearly all the output of Graham County in 1941 was old tailings, containing chiefly silver, lead, and copper, from the Grand Reef property in the Aravaipa district.

GREENLEE COUNTY

Ash Peak district (Duncan).—Lessees operated the Ash Peak and Hardy mines in 1941 and shipped a total of 9,533 tons of silver ore; the Ash Peak property was the largest producer.

Copper Mountain district (Morenci).—The metal output of the Copper Mountain district continued in 1941 to be principally copper ore and copper precipitates from the Morenci branch of the Phelps Dodge Corporation. The corporation treated 908,152 tons of copper ore in its testing concentrator and shipped 8,116 tons of copper precipitates. The remainder of the district output was mostly crude gold ore from the Gold Belt and Bianes & Pitts properties and gold-silver ore from the Emma Gomez claim.

According to the annual report of the Phelps Dodge Corporation for 1941, stripping operations at the Morenci branch removed 20,266,896 tons of material from the open pit; by the end of 1941, 49,183,602 tons of material in all had been removed from the pit, exclusive of ore mined for the test concentrator. As the year closed, stripping operations planned in advance of actual mining had been completed and the pit developed to permit a daily ore extraction of 25,000 tons. Railroad construction was pushed, and by December 31 about 60 percent of the main haulageway had been brought to its permanent position and the remaining 40 percent put in good operating condition. In the test-pit area a total of 1,002,315 tons of material comprising 943,493 tons of ore and 58,822 tons of waste was mined. Major construction projects completed in 1941, aside from the new reduction works, included 14 new dwellings, a 10,000,000-gallon reservoir to serve the new concentrator, installation of a new water-pipe line, and the building of a mine A. C.-D. C. substation. Virtually all essential buildings and shops at the reduction works were completed and occupied; the concentrator was about 90 percent finished, one unit of the power plant was nearly ready to run, and the smelting and converting plants were about 75 percent complete.

Mayflower district.—A little copper ore was produced in 1941 from the Providencia mine.

Metcalf (Greenlee) district.—The output of the Metcalf district in 1941 comprised 446 tons of crude zinc-lead ore from the Lime Cap mine, 61 tons of gold ore from the South Sycamore mine, and 23 tons of lead ore from the Midnight claim.

San Francisco district.—The American Gold placer property was worked a short time in 1941, and a little gold was recovered.

MARICOPA COUNTY

Big Horn district.—The principal production in the Big Horn district in 1941 was lode gold from the Big Horn mine and placer gold from the Davenport and Tiger properties.

Cave Creek and Camp Creek district.—The Red Rover mine on Camp Creek was operated the first 5 months of 1941, and about 1,500 tons of silver-copper ore were treated by flotation. The remainder of the district output was mainly gold ore from the Black Mountain, Edwards, and Defense properties.

Ellsworth (Harqua Hala) district.—Nearly all the output of the Ellsworth district in 1941 was copper ore from the Sonny and Columbia properties.

Gila Bend Mountains district.—Gold ore was produced in 1941 from the Blue Ribbon and Sunset properties near Gila Bend.

New River district.—A small lot of copper ore was produced in 1941 from the Daisy claim.

Osborn district.—Crude lead ore (545 tons) from the Belmont-McNeil mine was virtually the only output in the Osborn district in 1941; the mine was operated throughout the year by various lessees.

Pikes Peak (Morgan City) district.—There were 10 producers of gold ore in the Pikes Peak district in 1941, but most of the output came from the Pikes Peak group.

Salt River Mountains district.—The Delta mine, the only producer in the Salt River Mountains district in 1941, was operated continuously by the Park View Mining Co.; about 4,000 tons of gold ore were treated by flotation, and 141 tons of similar ore were shipped to a smelter.

San Domingo district.—Lessees operated the Gold Queen Standard property in 1941 and produced 20 tons of rich gold ore. The remainder of the district output was principally placer gold recovered by various operators working along San Domingo Wash.

Sunflower district.—Mining and milling were continued in 1941 at the Little Daisy mine; most of the output was gold ore treated by flotation.

Vulture district.—The chief output of the Vulture district in 1941, as in 1940, was gold ore from the Vulture mine. The East Vulture Mining Co. operated the mine continuously and treated 52,085 tons of gold ore and 8,140 tons of old tailings by cyanidation and concentration; it was by far the largest producer of gold in Maricopa County. The rest of the district output was largely crude gold-silver ore (4,295 tons) from the Newsboy (Pitt) mine.

White Butte district.—A little gold ore was produced in 1941 from the Charlotte claim near Phoenix.

Wickenburg district.—In 1941 about 3,700 tons of old tailings (gold) from a dump near Wickenburg were treated by cyanidation.

Winifred district.—All the output of the Winifred district in 1941 was gold ore, principally from the Jack White mine near Phoenix.

MOHAVE COUNTY

Cedar Valley district.—Complex ore from the Boriana mine continued in 1941 to be the principal output in the Cedar Valley district; 10,077 tons of ore were treated in a 120-ton concentration mill. Copper concentrates were shipped from the mill to a smelter in Arizona. Gold-silver ore and silver ore were produced at the Bunker Hill mine.

Chemehuevis district.—Small lots of gold ore were produced in 1941 from the Copper Ledge, Dutch Flat, and Gold Dome properties; placer gold was recovered from the Chief claim and "49" Diggings.

Cottonwood district.—About 200 tons of copper ore were shipped from the Copper Giant mine in 1941, and a little gold ore was produced from the Gold Mountain and North Star properties.

Gold Basin district.—There was a marked decline in output of gold in the Gold Basin district in 1941, owing to idleness of the cyanide mill at the Cyclopic mine and to closing of the concentration mill of the Malco Gold Mining Co. The chief production in 1941 was lode gold, mainly from the Golden Link, O. K., Excelsior, and M. O. properties, and placer gold from the Gold Basin Placers.

Indian Secret (White Hills) district.—More than 1,200 tons of ore were produced in the Indian Secret district in 1941; the output was all gold ore, silver ore, and gold-silver ore treated in a custom cyanide mill from various claims of the White Hills group.

Lost Basin district.—The entire output of the Lost Basin district in 1941 was placer gold and silver recovered by various operators working the Lost Basin Placers.

Maynard and McConnico district.—Production of gold in the Maynard and McConnico district increased in 1941, owing to mining and milling operations at the Bimetal mine by the W. H. M. Gold Mining Co. The gain in output of silver resulted from shipments of gold-silver ore from the Democrat mine.

Minnesota district.—About 3,700 tons of ore were produced in the Minnesota district in 1941, more than double that in 1940; 83 percent of the output was gold ore treated in a custom cyanide mill, from the Van Diemon, Yellow Aster, and Pope properties. The remainder was largely gold-silver ore from the Horn Silver mine.

Music Mountain district.—All the output of the Music Mountain district in 1941 was gold ore, principally from the Portland & Mizpah, Roosevelt, and Mohawk properties.

Owens (McCracken and Potts Mountain) district.—Numerous small lots of crude gold ore and copper-gold ore, produced from various claims in the Owens district in 1941, were sold to the Wickenburg Ore Market; however, the chief output was silver ore from the North Star mine, shipped to a smelter.

San Francisco (Oatman, Goldroad, Katherine, Vivian) district.—Production of gold in the San Francisco district was 42,098 fine ounces in 1941—a slight gain over 1940. The Goldroad mine of the United States Smelting, Refining & Mining Co. was by far the most important producer in the district; 154,436 tons of gold ore were treated in the company 300-ton cyanide plant in 1941 compared with 153,280 tons in 1940. The property again ranked fourth in gold production in the State.

Production of gold at Oatman, Goldroad, and Vivian in 1941 was 34,114 fine ounces compared with 32,044 in 1940, and that at Katherine was 7,984 ounces compared with 9,565; 94 percent of the gold output at Katherine came from the Tyro mine worked by the Gold Standard Mines Corporation. The company operated its 300-ton cyanide mill continuously, chiefly on gold ore (81,992 tons) from the Tyro mine. Other producers at Katherine included the Buellard, Burt, King of Secret Pass, Minnie, Philadelphia, and Sheep Trail properties. The chief producers of gold at Oatman and Vivian were the Vivian, Telluride, Western Apex, Pioneer, Gold Dust, and Sunnyside properties. The Vivian Mining Co. operated its 100-ton custom cyanide plant throughout the year, mainly on old tailings from the Vivian dump and on gold ore from the Vivian-Lelande Mitchell group; a total of 5,838 tons of old tailings and 4,377 tons of gold ore was treated.

Wallapai district (Cerbat, Chloride, Mineral Park, Stockton Hill).—Of the total ore (70,398 tons) produced in the Wallapai district in 1941, 64 percent was zinc-lead ore from the Tennessee mine operated by the Tennessee-Schuylkill Corporation. The company worked the mine continuously and treated 45,150 tons of zinc-lead ore in its 150-ton flotation mill—a decline of 10,371 tons from 1940; the mine ranked second in lead production in Arizona in 1941 and third in zinc. About 21 percent of the district output was gold ore, largely from the Tin Cup, Golden Gem, O'Brien, Golden Eagle, Rainbow, Red Seal, and Tintic properties. The remainder was chiefly gold-silver ore from the Nighthawk, C. O. D., Lucky Boy, Summit, Juno, and Mint properties; zinc ore from the Middle Golconda mine; silver ore from the Distaff and Silver Age mines; and lead ore from the Summit group. Concentration mills were operated at the C. O. D., Golden Gem, and Middle Golconda properties; and several thousand tons of gold ore, gold-silver ore, and silver ore were treated in the custom cyanide mill of Producers Mines, Inc.

Weaver (Mocking Bird, Pilgrim, Portland) district.—The output of ore and yield of gold and silver in the Weaver district in 1941 were much less than in 1940; the output of ore declined from 40,571 tons in 1940 to 18,858 tons in 1941, owing chiefly to the large decrease in output of gold ore from the Pilgrim mine of Producers Mines, Inc. The 300-ton cyanide mill owned by the company was operated almost exclusively on custom ores; a total of 46,540 tons of ore was milled in 1941 (2,322 tons of gold ore came from the Pilgrim mine). The most important producer in the district in 1941 was the Golden Door mine; 15,207 tons of gold ore were treated by cyanidation.

PIMA COUNTY

Ajo district.—Production of gold, silver, and copper in the Ajo district was much greater in 1941 than in 1940, owing to the large increase in output of copper ore from the New Cornelia mine, only producer in the district in 1941. The property remained the largest producer of copper in Arizona and ranked second in gold.

According to the annual report of the corporation for 1941, operations at the New Cornelia branch of the Phelps Dodge Corporation were at a maximum capacity (three-shift basis) throughout the year. Production at the open pit comprised 7,682,444 tons of copper ore and 7,232,688 tons of waste. The 22,500-ton concentrator treated 7,681,667 tons of copper ore with satisfactory metallurgy and with

improved unit efficiencies. The grinding capacity of the ball mills was increased, resulting in a greater output of copper concentrates.

Amole district.—Nearly all the output of the Amole district in 1941 was lead ore from the Old Yuma mine.

Arivaca district.—Various small-scale operators in the Arivaca district produced a total of 148 tons of ore in 1941; most of it was crude gold ore from the Oreona, Backbone, and Gold Plate properties.

Baboquivari district.—Operations at the Allison mine were greatly expanded in 1941, resulting in an increased output of gold ore. The property was operated continuously by the Gold Bar Mining Co. (formerly Tombstone Mining Co.) and 7,720 tons of gold ore were treated by cyanidation. The rest of the district output was small lots of crude gold ore from various prospects.

Cababi (Comobabi) district.—There were 11 producers in the Cababi district in 1941, but the chief output was gold ore from the Jaeger, Grand Central, Sophia, and Wayne properties.

Cerro Colorado district.—A small lot of silver-lead-copper ore was produced in 1941 from the Mary "G" claim.

Empire district.—Small lots of lead ore were produced in 1941 from the Esperanza, Chief, and Virgin properties.

Greaterville district.—The principal output of the Greaterville district in 1941 was placer gold recovered from the Greaterville Placers.

Helvetia (Rosemont) district.—About 420 tons of copper ore and a little lead ore were produced in the Helvetia district in 1941; the chief producer was the Copper World (Leader) mine.

Old Hat district (Oracle).—Continuous mining and milling operations throughout 1941 at the Daily and Geeseman groups by Control Mines, Inc., resulted in a greater output of silver and copper in the Old Hat district in Pima County. The company treated 29,200 tons of copper ore by flotation in 1941 compared with 24,000 tons in 1940. A little copper ore was produced also from the Apache mine.

Pima (Sierritas, Papago, Twin Buttes) district.—The output of the Pima district in 1941 was largely silver ore from the Black Silver property near Sahuarita.

Roskruge and Waterman (Silver Hill) district.—A lessee operated the Silver Hill mine in 1941 and shipped silver-copper ore and silver-lead ore to various smelters.

Silver Bell district.—Nearly all the output of the Silver Bell district in 1941 was silver-lead ore from the Indiana mine.

PINAL COUNTY

Bunker Hill district (Copper Creek).—In 1941 the Bunker Hill mine, operated by the Ari-Butte Operating Co., was the only producer in the Bunker Hill district; the output was mainly lead-copper ore treated by flotation.

Casa Grande district.—Output of silver in the Casa Grande district showed a marked increase in 1941, owing to steady shipments throughout the year of silver ore from the Silver Reef mine; 2,335 tons of ore were shipped to the smelter at Superior The remainder of the district output was chiefly silver-copper ore from the Reward mine.

Cottonwood and Black Mountain district.—Nearly all the ore produced in the Cottonwood and Black Mountain district in 1941 was crude gold ore from the Grand Prize mine.

Goldfields (Superstition Mountains) district.—In 1941, as in 1940, the principal output of the Goldfields district was old tailings (gold) from the Bulldog dump and first-class gold ore from the Superstition mine.

Mineral Creek district (Ray).—Operations at the Ray mine of the Nevada Consolidated Copper Corporation were expanded in 1941, resulting in a marked increase in output of copper. The company reported that 2,882,406 tons of copper ore were treated in the company 12,000-ton concentrator in 1941 compared with 2,103,004 tons in 1940. In addition, 7,820 tons of copper precipitates were shipped to the smelter at Hayden; the property ranked fourth in copper production in Arizona in 1941. The district output of gold decreased considerably in 1941, owing to suspension of operations at the Broken Hill gold mine in June 1940.

Mineral Hill district.—Production in the Mineral Hill district in 1941 totaled 1,157 tons of ore—a decline of 41 percent from 1940. The principal output was crude gold ore from the Sunset, Wedge, Kitty Why, Troxel, and Consolidated Gold properties.

Old Hat district (Oracle).—Mining and milling operations at the Mammoth-St. Anthony & New Year-Mohawk groups were continuous throughout 1941; the output (192,977 tons) of ore was slightly greater than in 1940. The ore was treated by gravity concentration, followed by flotation, and the flotation tailings were treated by cyanidation. Lead concentrates containing considerable quantities of gold and other metals were smelted in the company 20-ton lead furnace, and gold precipitates were shipped to an eastern refinery. The property was the largest producer of gold from siliceous gold ore in Arizona in 1941 and ranked third in lead output. The remainder of the district output was largely crude gold ore from the Southern Belle mine.

Owl Head district.—The San Antonio No. 1 claim near Oracle was operated in 1941, and 77 tons of silver ore were shipped to a smelter.

Pioneer district (Superior).—Copper ore and zinc-copper ore from the Magma mine were, as usual, the chief output in the Pioneer district in 1941. The Magma Copper Co. operated its mine, 850-ton concentrator, and 450-ton copper smelter continuously, except for the usual summer shut-down. According to the company printed annual report, the mill treated 245,885 tons of copper ore averaging 5.26 percent copper and 80,810 tons of zinc-copper ore averaging 1.77 percent copper and 8.16 percent zinc; in addition, 78,177 tons of copper ore were sent direct to the smelter. Production, after all losses (including refining) were deducted, was 11,741 ounces of gold, 631,189 ounces of silver, 37,152,224 pounds of copper, and 7,715,313 pounds of zinc. The average net cost of producing copper after deduction of gold, silver, and zinc concentrate values was 7.9 cents a pound. Stoping operations were carried on at the usual rate until September 1, when production was speeded for defense purposes; an increase of about 15 percent was attained by October 1. The rest of the district output was largely crude silver ore (9,124 tons) from the Reymert mine and crude gold ore (4,765 tons) from the Lake Superior & Arizona property.

Ripsey district.—Gold-silver ore (502 tons) from the Norman group (Old Ripsey) was the only output in the Ripsey district in 1941.

Saddle Mountain district.—A little copper ore was produced in 1941 from the Senator mine and gold ore from the Columbia No. 1 claim.

SANTA CRUZ COUNTY

Harshaw district.—Zinc-lead-silver ore from the Trench and Flux groups was by far the principal output in the Harshaw district in 1941. The American Smelting & Refining Co. operated both groups and its 200-ton concentrator continuously; about 67,300 tons of ore were treated in 1941 compared with 49,311 tons in 1940. The company was again the largest producer of lead in Arizona and ranked second in zinc. The remainder of the district output was chiefly crude silver ore from the American, Salvador, and World's Fair properties.

Nogales (Gold Hill) district.—Nearly all the output of the Nogales district in 1941 was gold-silver ore from the Roy mine and gold ore from the Louella Lou, Hardscrabble, and Silent Friend properties.

Oro Blanco district (Ruby).—Production in the Oro Blanco district in 1941 was 1,411 tons of ore, a marked decline from 54,564 tons in 1940. This large loss resulted from suspension of operations at the Montana zinc-lead-silver property in May 1940. The district output in 1941 was largely gold-silver ore from the Old Soldier and Noon properties, silver ore from the Brick claim, and gold ore from the Oro Blanco mine.

Palmetto district.—In 1941 about 170 tons of copper ore from the Three R mine were concentrated, and a small lot of crude silver-lead ore from the La Palma claim was sold to a local ore buyer.

Patagonia (Duquesne) district.—The increased output of silver, copper, lead, and zinc in the Patagonia district in 1941 resulted from continuous mining and milling operations at the Duquesne property by the Callahan Zinc-Lead Co. The company reported that 27,572 wet tons of zinc-lead-copper ore were treated by flotation in 1941 and that 1,109 tons of silver-lead-copper concentrates and 696 tons of copper concentrates were shipped to El Paso, Tex., and 3,601 tons of zinc concentrates to Amarillo, Tex. The rest of the district output was mainly copper ore from the Gladstone, Paymaster, and Quajalote properties and lead ore from the Mowry mine.

Tyndall district.—Nearly all the output of the Tyndall district in 1941 was crude lead ore from the Jefferson mine and lead-silver ore and lead-copper ore from the Alto group.

Wrightson district.—A little silver ore was produced in 1941 from the Armada and Lucky Strike claims and a small lot of copper ore from the American Boy prospect.

YAVAPAI COUNTY

Agua Fria district.—The Burzog (Old Minor) property was operated in 1941, and 1 car of copper ore was shipped to a smelter.

Ash Creek district.—Lessees worked the Gold Coin mine in 1941 and produced 145 tons of first-class gold ore.

Big Bug district.—There was a marked increase in production of gold and silver and a gain in copper and zinc but a decline in lead in the Big Bug district in 1941. The principal output in 1941 was zinc-lead-gold-silver ore from the Iron King mine at Humboldt; 69,159 tons of zinc-lead ore were treated by flotation, 60,206 tons of current flotation tailings (gold-silver) were treated by cyanidation, and 6,419 tons of crude gold-silver ore were shipped to a smelter. The remainder of the district lode output was chiefly crude gold ore (1,956 tons) from the Postmaster mine. The output of placer gold was 6,056 fine

ounces—an increase of 4,652 ounces over 1940; the gain resulted from operation of a dragline floating dredge at the Star (Lawson) property by Arical Mines, Inc. The Big Bug Dredging Co. operated a dragline floating dredge at the Hill property until March 12, when it was moved to a property in the Lynx Creek district.

Black Canyon district.—The output of ore and yield of gold, silver, copper, and lead in the Black Canyon district were less in 1941 than in 1940, owing to the large decrease in output of gold-silver-lead ore from the Golden Turkey group near Cordes; the output dropped from 43,544 to 27,283 tons. The remainder of the district output was largely silver ore from the Silver Cord and Thunderbolt mines.

Black Hills district.—Gold ore was produced in 1941 from the Ambassador and D. & M. mines and copper ore from the Yeager claim.

Black Rock district.—The output of the Black Rock district in 1941 was principally gold ore from the Super X (Atos) mine, treated in a cyanide mill. Numerous small lots of crude gold ore and copper-gold ore were produced from various claims and sold to the Wickenburg Ore Market; placer gold was recovered chiefly from the Justin Placers.

Blue Tank district.—Small lots of gold ore were produced in 1941 from the Franklin D. and Lone Star claims and copper ore from the Little Mildred and McIntosh properties.

Bullard (Pierce) district.—Bullard Gold Mines, Inc., worked the Bullard mine continuously in 1941 and shipped about 1,800 tons of gold-copper ore to a smelter. The rest of the district output was mainly copper ore from the Little Giant mine.

Castle Creek district.—The principal output of the Castle Creek district in 1941 was crude lead ore from the Montezuma and Palona King properties and gold ore from the Gold Rock and King Bolt mines.

Cherry Creek district.—All the output of the Cherry Creek district in 1941 was crude gold ore shipped to smelters; the chief producers were the Sugar Bowl, Sensation, Black Hawk, Volcano, Gray Eagle, and Gold Pick properties.

Copper Basin district.—Placer gold was the principal output in the Copper Basin district in 1941; the Queen of Sheba claim was the largest producer.

Eureka district.—Production of gold, silver, copper, lead, and zinc in the Eureka district in 1941 was much greater than in 1940, owing to increased output of zinc-lead ore from the Hillside mine and copper ore from the Bagdad property. All of the zinc and most of the gold, silver, and lead output of the district were recovered from the treatment of 31,450 tons of zinc-lead ore from the Hillside mine, and nearly all the copper output was recovered from the treatment of 88,209 tons of copper ore from the Bagdad property.

Hassayampa (Groom Creek, Hassayampa River, Senator, Prescott) district.—About 1,700 tons of ore were produced in the Hassayampa district in 1941 compared with 2,512 tons in 1940; most of it was gold ore from the Climax Extension, Oro Flame, Alma, Eureka, Railroad, Sacramento, Big Chief, Mohawk, U. P., Golden Summer, Nevada, and Infanta properties. The most important producer was the Oro Flame mine. Placer gold was recovered chiefly at the Hobbs property by a dragline floating dredge working the last 10 days of the year.

Humbug district.—A little gold ore was produced in 1941 from the Humbug Gold Mines property, and 139 tons of old tailings (gold)

were shipped from a dump; placer gold and silver were recovered by various operators working along Cow, French, and Humbug Creeks.

Kirkland district.—All the output of the Kirkland district in 1941 was crude gold ore, mainly from the Venus mine.

Lynx Creek district.—The output of placer gold in the Lynx Creek district was 4,372 fine ounces in 1941, an increase of 2,342 ounces over 1940. The gain resulted from operation of a dragline flotation dredge at the Peach & Brown property by the Big Bug Dredging Co. The rest of the district placer gold was recovered, chiefly by dredges, at the Fitzmaurice and Speck-Lynx Creek properties.

Martinez (Congress) district.—Gold and silver recovered from old tailings and waste-dump ore at the Congress property continued in 1941 to be the chief production of the Martinez district; 49,712 tons of ore and 50,068 tons of old tailings were treated by cyanidation in 1941 compared with a total of 91,307 tons of ore and old tailings in 1940.

Peck district.—In 1941 crude silver ore (223 tons) from the Swastika mine was the only output in the Peck district.

Pine Grove district (Crown King).—The Gladiator Mining Co. worked the Gladiator-War Eagle group throughout 1941 and shipped 4,759 tons of gold ore containing some silver and copper. The remainder of the district output was principally gold ore and old tailings from the Golden Crown property and crude gold-lead ore from the Del Pasco mine.

Silver Mountain district (Wagoner).—Nearly all the output of the Silver Mountain district in 1941 was crude silver ore from the Little Joker mine.

Squaw Creek district.—A little gold ore was produced in 1941 from the Gold Crown claim near Canyon.

Tiger district.—About 262 tons of gold ore and 22 tons of gold-silver ore were produced in the Tiger district in 1941; the chief producers were the Oro Belle, Fortuna, and Pilgrim properties.

Turkey Creek district.—The principal output of the Turkey Creek district in 1941 was crude gold ore from the Issaquah, Parker, and Cumberland properties.

Verde district (Jerome).—Production of gold, silver, and copper in the Verde district was much greater in 1941 than in 1940, owing to increased output of copper ore from the United Verde mine of the Phelps Dodge Corporation; the total output of ore and old tailings from the property was 1,097,546 tons in 1941 compared with 882,319 tons in 1940.

According to the printed annual report of the corporation for 1941, the United Verde mine produced 838,454 tons of copper ore from underground operations; as in past years, a large part of the total ore mined was recovered from pillars. Stoping operations were much larger than in 1940, and all available ore areas were worked to the extent possible under proper mining sequence. Total development for the year amounted to 20,597 feet, including 15,653 feet of diamond drilling and 656 feet of sinking at the No. 8 shaft. Material reclaimed from ore dumps totaled 239,318 tons, production of precipitates amounted to 690 tons, and the concentrator treated 651,552 tons of copper ore.

Lessees continued to work the Iron King-Equator group and shipped 20,580 tons of gold-silver ore to a smelter. The rest of the district output was principally crude copper ore from the Green Flower property.

Walker district.—About 8,360 tons of ore were produced in the Walker district in 1941—a marked increase over 1,668 tons in 1940; nearly 96 percent of the output was gold-silver-copper ore concentrated from the Sheldon property. The remainder was largely crude gold ore from the Four Boys, Oro Plata, Alturas, Lost Wonder, and Emma properties. Placer gold and silver were recovered by various small-scale operators working on Lynx Creek near Walker.

Walnut Grove district.—Nearly all the output in the Walnut Grove district in 1941 was crude copper ore from the Copper Crown and Red Devil claims and gold ore from the Granite group.

Weaver district (Octave).—Production of gold in the Weaver district was 20,190 fine ounces in 1941, a gain of 871 ounces over 1940; 94 percent of the total came from three properties—the Octave, Alvarado, and Yarnell. The most important producer continued to be the Octave mine, operated by the American Smelting & Refining Co.; 27,951 tons of gold ore were treated by flotation, and the flotation tailings were cyanided. About 40,150 tons of gold ore from the Yarnell mine and 36,372 tons of similar ore from the Alvarado mine were treated in cyanide plants. Other producers of gold ore included the Johnson, "94," Rincon, Monica, York (Rees), and Koerber properties. Placer gold was recovered chiefly from the Sunshine, Merrill, and Home claims.

White Picacho district.—The Eugenia group was operated in 1941, and 446 tons of crude copper-silver ore were shipped to a smelter. The rest of the district output was mainly gold ore from the Young property.

YUMA COUNTY

Castle Dome district.—The most important output in the Castle Dome district in 1941 was placer gold recovered at the Ocatilla property by a Stebbins dry concentrator. The chief producer of lode gold was the Southern Extension mine.

Cienega district.—Lessees operated the Empire mine in 1941 and shipped 325 tons of gold-copper ore to various smelters in Arizona. The rest of the district output was mainly crude gold ore from the Golden Ray group.

Dome (Gila City) district.—All the output of the Dome district in 1941 was placer gold recovered by various operators working along the Gila River near Dome.

Ellsworth district (Salome).—Of the total ore (659 tons) produced in the Ellsworth district in 1941, about 45 percent was numerous small lots of crude gold ore and gold-copper ore sold to the Wickenburg Ore Market. The remainder was principally crude copper ore from the Moore group and gold ore from the Bunker Hill, Critic, Dandy, and Hercules properties, shipped to a smelter.

Eureka district.—The Penn Metals, Inc., operated the Red Cloud mine a few months in 1941 and treated about 3,300 tons of lead-silver ore by flotation.

Kofa district.—Small lots of ore averaging 10 ounces of gold to the ton were produced in 1941 from the Oakland claim; gold ore was produced also from the Blue Bird, Katy Ross, and Sheep Tanks properties. Placer gold was recovered from the Kofa claim.

Laguna district.—In 1941, as in 1940, all the output of the Laguna district was placer gold recovered by various operators working in the Laguna Dam area.

La Paz and Middle Camp district.—The principal output in the La Paz and Middle Camp district in 1941 was placer gold recovered largely from the Golden Anchor (Jones) property. Small lots of high-grade gold-copper ore were produced from the Copper Bottom claim.

Mohawk district.—The Red Cross mine was operated in 1941, and 33 tons of silver ore were shipped to a smelter.

Plomosa and La Cholla district.—A total of 1,771 tons of ore was produced in the Plomosa and La Cholla district in 1941 compared with 3,017 tons in 1940. The chief output was crude gold ore from the Little Butte mine and crude silver ore from the R. & A. property. The marked decrease in output of placer gold resulted from suspension in February of drift mining at the Arizona Drift property. Other placer producers included the Can Do (Erdman) and Yell claims.

Santa Maria (Planet, Bill Williams) district.—The only output in the Santa Maria district in 1941 was old mill clean-up material containing chiefly copper from the Swansea property.

Trigo district.—All the output of the Trigo district in 1941 was placer gold recovered by various operators working gravel in dry washes.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN CALIFORNIA

(MINE REPORT)

By Charles White Merrill and H. M. Gaylord

SUMMARY OUTLINE

SUMMARY

After an uninterrupted rise from $12,066,750 in 1932 to $54,268,690 in 1940, the total value of gold, silver, copper, lead, and zinc produced from California ore, old tailings, and gravels declined in 1941 to $52,231,066 (see fig. 1). Higher wages, migration of miners to war industries, rising prices of supplies and materials and difficulties in obtaining them, increased taxes, and fixed prices for gold and silver (the most important of the five metals in California) were factors in reversing the upward trend that had more than quadrupled in 8 years the value of the metals covered by this survey.

Comparing 1941 with 1940, the decline in total value for the five metals was 4 percent; gold decreased 3 percent and silver 9 percent in both quantity and value, copper decreased 39 percent in quantity and 36 percent in value, lead increased 95 percent in quantity and 123 percent in value, and zinc increased 457 percent in quantity and 563 percent in value. Of the total value of the five metals in 1941, gold represented 94 percent, silver 3 percent, copper 2 percent, and lead and zinc combined 1 percent.

Despite a 10-percent decline for 1941 in total value of production, Nevada County continued to be the largest contributor to the metal-mining output of California; it supplied 20 percent of the State total value of the five metals, 20 percent of the total gold, and 39 percent of the lode gold. Sacramento County (largely from gold dredging) contributed 12 percent of the total value of the five metals; Amador County (three-fourths from gold ore and one-fourth from placer gravels) and Kern County (largely from gold and gold-silver ores), 7 percent each; Yuba County (largely from gold dredging) and Butte County (largely from placer gravels), 6 percent each; Calaveras County (almost two-thirds from gold ore and one-third from placer gravels) and Siskiyou County (largely from placer gravels), 5 percent each; and Plumas County (largely from gold and copper ores), 4 percent. Thus, the foregoing 9 of the 40 counties producing the metals in California in 1941 contributed over 2 million dollars each to the State total value and supplied nearly three-fourths of that total.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937-41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0 7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052
1940	35.00	[6] .711+	.113	.050	.063
1941	35.00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938-41: Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in California, 1937-41, and total, 1848-1941, in terms of recovered metals

Year	Mines producing [1]		Ore, old tailings, etc. (short tons)	Gold (lode and placer)		Silver (lode and placer)

[1] For data by years before 1937 see Minerals Yearbook, Review of 1940, p. 219.
[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property worked.
[3] First year for which this method was reported used in California.
[4] Includes all placer operations using suction pump for delivering gravel to floating washing plant, except those producing less than 100 ounces of gold which are included under "Small-scale hand methods."
[5] Includes all placer operations using power excavator and washing plant, both on dry land; when washing plant is movable, outfit is termed "dry-land dredge."
[6] Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dip boxes, pans, rockers, dry washers, etc.
[7] Figures changed to exclude suction dredges. See footnote 4.
[8] Revised figures.
[9] A mine using more than 1 method of recovery is counted but once in arriving at total for all methods.
[10] Complete data not available.

Gold.—After an uninterrupted rise from 1929 to 1940, the quantity and value of California gold production in 1941 fell below that of 1940. The reversal in trend was due entirely to the decline in lode mining; placer-gold output continued to rise and exceeded that for any year since 1862.

The 25 leading gold-producing mines in California in 1941, listed in the following table, yielded 54 percent of the total gold output of the State. In 1941, three lode mines (gold ore) and two placers (connected-bucket dredges) displaced two lode mines (gold ore) and three placers (two connected-bucket dredges and one dragline dredge) which were on the 1940 list; of those displaced, one connected-bucket dredge and the dragline-dredge operations were reported worked out and one of the lode operations lost its identity by merger with its neighbor.

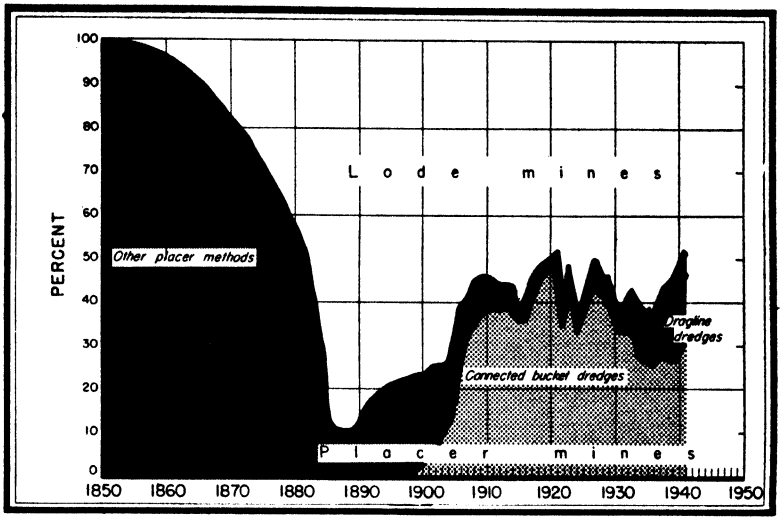

FIGURE 2.—Percentage of total California gold produced at lode and placer mines and by various methods of placer mining, 1850–1941.

Twenty-five leading gold-producing mines in California in 1941, in order of output

Rank	Mine	District	County	Rank in 1940	Operator	Source of gold
1	Idaho Maryland-Brunswick.	Grass Valley-Nevada City.	Nevada	1	Idaho Maryland Mines Corporation.	Gold ore.
2	Natomas Co.	Folsom	Sacramento	3	Natomas Co.	Dredge.

23	Merced dredge	Snelling	Merced	28	Merced Dredging Co.	Dredge.
24	Putnam property	Camanche	San Joaquin	82	Gold Hill Dredging Co.	Do.
25	Siskiyou Unit	Callahan	Siskiyou	20	Yuba Consolidated Gold Fields.	Do.

Silver.—The bulk of the silver output of California in 1941 was more localized than that of the gold; the 10 leading silver-producing mines, listed in the following table, yielded 80 percent of the State total recoverable silver in that year. The list is similar to that of 1940, except for some changes in rank, the exclusion of the Iron Mountain mine (Shasta County) and the Standard mine (Mono County), and the inclusion of the Columbia No. 2 mine (Inyo County) and the Alabama mine (Placer County). In addition to the mines listed, some silver was recovered from almost every lode and placer mine operating in the State in 1941.

Ten leading silver-producing mines in California in 1941, in order of output

Rank	Mine	District	County	Rank in 1940	Operator	Source of silver
1	Cactus Queen	Mojave	Kern	1	Cactus Mines Co	Gold-silver ore.
2	Lava Cap	Grass Valley-Nevada City.	Nevada	2	Lava Cap Gold Mining Corporation.	Gold ore.
3	Golden Queen	Mojave	Kern	4	Golden Queen Mining Co.	Do.
4	Starlight	do	do	5	Lodestar Mining Co	Do.
5	Walker	Genesee	Plumas	3	Walker Mining Co	Copper ore
6	Columbia No. 2	Resting Springs	Inyo	12	Shoshone Mines, Inc	Lead ore.
7	Kelly	Randsburg	San Bernardino.	7	F. Royer and lessees	Gold-silver ore.
8	Empire Star Mines	Grass Valley-Nevada City.	Nevada	10	Empire Star Mines Co., Ltd	Gold ore.
9	Alabama	Ophir	Placer	11	Alabama California Gold Mines Co.	Do
10	Grigsby (Palisade)	Calistoga	Napa	6	Helena Consolidated Mines, Inc	Gold-silver ore

Copper.—Copper production in California decreased materially with the suspension of operations at the Walker mine in the Genesee district of Plumas County, October 31, 1941; during the year this mine contributed over 92 percent of the State copper output of 7,886,000 pounds.

Lead.—Lead production in California increased 95 percent in quantity and 123 percent in value in 1941 compared with 1940. Shoshone Mines, Inc., which operated the Columbia No. 2 mine in the Resting Springs district of Inyo County, and Imperial Metals, Inc., which operated the Black Eagle mine in the Eagle Mountain district of Riverside County until work was suspended early in the year, supplied 94 percent of the State total.

Zinc.—Zinc production in California, although still very small, increased 457 percent in quantity and 563 percent in value in 1941 compared with 1940; 96 percent of the zinc was recovered from ores shipped by E. H. Snyder from the Colorado group in the Modoc district of Inyo County and by W. F. Houston from the Carbonate King mine in the Ivanpah district of San Bernardino County. Much of the ore from both mines was converted to zinc oxide at the Richmond plant of the Western Zinc Oxide Co (operated under lease after September 18, 1941, by the Pacific Zinc Oxide Co.).

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in California in 1941, by counties, in terms of recovered metals

County	Mines producing [1]		Gold					
			Lode		Placer		Total	
	Lode	Placer	Fine ounces	Value	Fine ounces	Value	Fine ounces	Value
Alpine	1		136	$4,760			136	$4,760

MINING INDUSTRY

The tonnage of material from lode mines in California treated in 1941 decreased 8 percent compared with 1940, but the yardage at placer mines increased 4 percent; the output of lode gold declined 8 percent, but that of placer gold rose 2 percent. The average grade of lode material remained unchanged, but the average recoverable gold content of gravels declined 2 percent. Of the State total gold output in 1941, 49 percent was from lode mines and 51 percent from placers; this was the first year since 1927 that placer-gold production had exceeded that from lode mines.

Dredges of the connected-bucket type handled 71 percent of the gravel mined and recovered 58 percent of the State total placer gold in 1941.

The next most important method of placer mining—dragline dredging—continued in 1941 its spectacular rise as a means of recovering gold. The first dragline-dredge production in the United States was reported in California in 1933, when three outfits began work late in the year and recovered less than 100 ounces of gold. In 1941, 112 dragline dredges worked 234 properties; they washed 24 percent of the total placer gravel and recovered 31 percent of the total placer gold. The following table gives partial data on equipment in the dragline-dredge industry over a 3-year period; information on bucket size was supplied for 52 dredges in 1939, 89 in 1940, and 94 in 1941.

Size of buckets (cubic yards)	Number of boats			Size of buckets (cubic yards)	Number of boats		
	1939	1940	1941		1939	1940	1941
7½		1		1¾	2	3	8
6	1		2	1½	17	25	19
5		2	6	1¼	5	9	6
4		1		1	4	9	6
3½	1			⅞			1
3	3	4	5	¾	1	7	8
2½	4	8	19	½	2	3	
2¼	2	1	1	⅜		1	
2	10	15	13				

The Becker-Hopkins type of dredge (single bucket on telescopic arm attached to dredge) made its first appearance in California in 1940, when units were installed in Fresno and Sacramento Counties. In 1941 two of these dredges worked two properties in Sacramento County and one in Butte County.

A small increase was reported in gold recovery and a small decrease in quantity of gravel handled at nonfloating washing plants to which

gravel was delivered by mechanical means. Equipment was moved from one property to another, as was the practice with dragline dredges, and 76 plants worked 85 properties. Some of these nonfloating washing plants are stationary; others are built to move on skids, wheels, tracks, or by other means. Dragline excavators, power shovels, slackline excavators, trucks, bulldozers, and other machines are used to deliver the gravel.

Hydraulic production of gold in 1941 declined compared with 1940, but the quantity of gravel washed increased. Output by small-scale hand methods (both wet and dry) and by drift mining decreased.

Consumption of quicksilver at California placer mines totaled 19,949 pounds in 1941 compared with 21,872 pounds in 1940. The following quantities of gold were recovered to the pound of quicksilver used in 1941 (1940 figures in parentheses): Connected-bucket dredging, 40 ounces (41); dragline dredging, 37 ounces (39); nonfloating washing plants with mechanical gravel handling, 42 ounces (10); hydraulicking, 22 ounces (12); small-scale hand operation, 15 ounces (15); and drift mining, 72 ounces (115).

ORE CLASSIFICATION

Of the 4,280,185 tons of ore (including 845,076 tons of old tailings) sold or treated in 1941, 90 percent was dry gold ore and old tailings, 7 percent copper ore, and most of the remainder dry gold-silver ore.

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore and old tailings sold or treated in California in 1941, with content in terms of recovered metals

METALLURGIC INDUSTRY

During 1941, as in former years, most of the ore and virtually all the old tailings were treated at amalgamation and cyanidation mills (with or without concentrating equipment); 90 percent of the total

ore and old tailings was treated at such mills in 1941. Almost all the remaining ore was treated at concentrating mills; only 44,810 tons of crude ore and 9 tons of old tailings were shipped for direct smelting. Smelters received 32,198 tons of flotation concentrates and 2,422 tons of gravity concentrates from California mine operators in 1941. Comparing 1941 with 1940, ore treated at amalgamation and cyanidation mills decreased 9 percent, quantity of old tailings treated remained virtually unchanged, quantity of material treated at concentrating mills decreased 20 percent, and quantity of crude ore and old tailings smelted increased 54 percent.

Quicksilver consumption at California amalgamation mills totaled 7,265 pounds, used in the treatment of 2,104,298 tons of material to recover 285,038 ounces of gold and 65,978 ounces of silver in 1941. In the treatment of 1,265,201 tons of ore, 838,135 tons of old tailings, and 3,996 tons of concentrates to recover 203,511 ounces of gold and 600,949 ounces of silver, cyanide consumption was 289,659 pounds of 91-percent sodium cyanide and 1,812,239 pounds of commercial calcium cyanide (50-percent NaCN equivalent); in terms of 98-percent NaCN, the consumption was 1,193,581 pounds or 0.57 pound to the ton. A substantial part of the cyanide was consumed at custom mills in California.

Companies producing most of California's lode gold in 1941 owned and operated their own metallurgical plants, but a number of custom mills were active. The leading operators of metallurgical plants receiving custom material were: Burton Bros., Inc., Rosamond, Kern County; Golden Queen Mining Co., Mojave, Kern County; Mineral Reduction Co., Benton, Mono County; Gold Crown Mining Co., Ltd., east of Twentynine Palms, San Bernardino County; and F. W. Royer, Red Mountain, San Bernardino County. All these mills were cyanidation plants and accepted ore and old tailings for treatment. The Idaho Maryland Mines Corporation and Empire Star Mines Co., Ltd., Grass Valley, Nevada County, cyanided some lots of concentrates. The largest metallurgical custom plant in California—the Selby lead plant of the American Smelting & Refining Co. at Selby, Contra Costa County—continued to be the State's only smelter.

Mine production of metals in California in 1941, by methods of recovery, in terms of recovered metals

[1] Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; others producing listed in footnote 17 and their output included under "Other districts."
[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[3] Source of total silver as follows. 2,088,713 ounces from lode mines and 65,475 ounces from placers.
[4] Camanche district lies in Amador, Calaveras, and San Joaquin Counties.
[5] East Belt district lies in Amador, Calaveras, Eldorado, Mariposa, and Tuolumne Counties.
[6] Mother Lode district lies in Amador, Calaveras, Eldorado, Mariposa, and Tuolumne Counties.
[7] Included under "Other districts."
[8] Exclusive of lode output, which is included under "Other districts."
[9] Output of property not classed as a "mine."
[10] Jenny Lind district lies in Calaveras and San Joaquin Counties.
[11] Includes metals from tungsten concentrates from ore not included in "Ore and old tailings" tonnage.
[12] Randsburg district lies in Kern and San Bernardino Counties.
[13] Chowchilla River district lies in Madera and Merced Counties.
[14] Hunter Valley district lies in Mariposa and Merced Counties.
[15] Exclusive of placer output, which is included under "Other districts."
[16] Dale district lies in Riverside and San Bernardino Counties.
[17] Includes following: Butte Creek district (lode) in Butte County; Jenny Lind (lode) in Calaveras County; Davis Flat in Fresno County; Resting Springs in Inyo County; French Corral (placer) in Nevada County; Genesee (lode), Greenville (placer), and Rich Bar in Plumas County; Holcomb Valley (lode), Randsburg (placer), and Ship Mountain in San Bernardino County; French Gulch (placer) in Shasta County; Depot Hill, Gold Lake (placer), and Port Wine in Sierra County; Coffee Creek and Hayfork (lode) in Trinity County.

ALPINE COUNTY

Monitor district.—Lessees worked the Zaca mine during 1941; the principal product was gold concentrates shipped to a smelter.

AMADOR COUNTY

Camanche district.—The Independence Gold Mines treated 12,100 cubic yards of gravel at a stationary washing plant between July 30 and October 12, 1941, recovering 187 ounces of gold and 19 ounces of silver.

East Belt district.—The Belama Corporation worked the Belden mine in the Volcano section of the East Belt during 1941 and treated 4,069 tons of ore in a 25-ton flotation mill; amalgamation, cyanidation, and smelting of concentrates yielded 2,079 ounces of gold and 634 ounces of silver. E. Schaefer shipped 145 tons of ore, containing 458 ounces of gold, 276 ounces of silver, and 2,575 pounds of copper, from the Elkhorn mine to a smelter. The Gwalia Gold Mining Co. worked the Pioneer mine and recovered gold by amalgamation and the smelting of flotation concentrates. Kent & Nimmo treated 1,500 tons of ore at the Three-in-One mine; bullion containing 170 ounces of gold and 51 ounces of silver was recovered by amalgamation, and table concentrates containing 18 ounces of gold, 15 ounces of silver, and 145 pounds of copper were shipped to a smelter. Garibaldi Bros. operated a nonfloating washing plant, to which gravel was delivered by mechanical means, at the Garibaldi mine, Pioneer Creek, one-half mile east of Volcano, intermittently during 1941; 33,200 cubic yards of gravel yielded 229 ounces of gold and 35 ounces of silver. The River Pine Mining Co. operated a dragline dredge near Aukum, which used a dragline excavator with a 1¾-cubic yard bucket, from January 1 to June 12, when it was moved to a site in Eldorado County near Nashville; 300,000 cubic yards of gravel yielded 1,380 ounces of gold and 192 ounces of silver.

Ione district.—The Amador Dredging Co. operated a dragline dredge in the Ione district during 1941. The Arroyo Seco Gold Dredging Co. operated an electric connected-bucket dredge, equipped with eighty-six 6-cubic foot buckets, from January 1 to May 15. The Lancha Plana Gold Dredging Co. operated an electric connected-bucket dredge, equipped with sixty-five 4½-cubic foot buckets, on Jackson Creek near Buena Vista from January 1 to May 4, when it was dismantled and moved to Butte Creek, Butte County. H. G. Kreth operated the Horton mine in Jackson Valley 5 miles south of Ione by hydraulicking from January to June and from October to December. McQueen and Downing operated a dragline dredge at the Irish Hill mine from March 28 to June 25. Lorentz and Swingle operated a dragline dredge on the Cosumnes River 7 miles northwest of Plymouth during 1941. The Pacific Placers Engineering Co. operated a dragline dredge with an electric dragline excavator, which used a 2½-cubic yard bucket, on the McCulloh property from January 1 to February 8 and from May 13 to December 31; 350,000 cubic yards of gravel yielded 2,749 ounces of gold and 258 ounces of silver. The Rim Cam Gold Dredging Co. operated a dragline dredge on the Yager ranch from February 4 to May 26.

Mother Lode district.—The Argonaut Mining Co., Ltd., operated the Argonaut mine throughout 1941; gold ore was treated by amalgama-

tion and flotation. During the year the company installed a 10-ton cyanide plant to handle concentrates from the Argonaut mine and the nearby Plymouth property, where it had treated old tailings by flotation; until this cyanide plant was put into operation, the concentrates were shipped to a smelter. The Central Eureka Mining Co. operated the Central Eureka and Old Eureka mines; the ore was treated by amalgamation and flotation, and the sands and concentrates were cyanided. The Black Hills Mining Co. worked the Italian mine. The Kennedy Mining & Milling Co. operated the Kennedy mine throughout 1941; gold ore was treated by amalgamation and flotation, and the concentrates were shipped to a smelter. The Keystone Mine Syndicate worked the Keystone mine; 97,945 tons of ore were treated in the company 300-ton amalgamation-flotation mill; 1,984 ounces of gold were recovered in bullion, and 9,226 ounces were contained in 747 tons of concentrates shipped to a smelter. The Delta Tailings Co. continued to cyanide material derived from old tailings collected in the channel of one of the streams draining a section of the Mother Lode district; two such deposits were worked during 1941. Henry & Weaver operated a dragline dredge, equipped with a dragline excavator and a ¾-cubic yard bucket, on the Allen ranch on Sutter Creek Gulch from November 22 until December 12. On Little Indian Creek 4 miles west of Plymouth W. D. Ingram operated a dragline dredge, which had two dragline excavators—one with a 2½-cubic yard and the other with a 1-cubic yard bucket -from January 1 to May 11; the tailings were leveled and the overburden replaced, fitting the land for further agricultural use. The Mountain Gold Dredging Co. operated a dragline dredge with a dragline excavator, using a 1½-cubic yard bucket, on the Matulich property in the Drytown section of the Mother Lode intermittently during 1941. W. D. Ingram and the Mountain Gold Dredging Co. operated dragline dredges on the W. F. Detert estate also during 1941. J. C. Pantle operated a dry-land dredge on the Rupley ranch on Willow Creek; 360,000 cubic yards of gravel yielded 1,850 ounces of gold and 254 ounces of silver. E. L. Lilly operated a dragline dredge, which employed a dragline excavator with a 2¼-cubic yard bucket, on the Treble Clef mine from January 1 to June 14 and from July 2 to December 16.

BUTTE COUNTY

Butte Creek district.—The Lancha Plana Gold Dredging Co. moved its connected-bucket dredge from Amador County to Butte County and resumed operations October 22, 1941. The Piedmont Dredging Co. operated a Becker-Hopkins type dredge on Butte Creek intermittently from September 24 until the end of the year; 29,592 cubic yards of gravel yielded 121 ounces of gold and 10 ounces of silver.

Magalia district.—S. F. Thomas operated the S & D mine from January 1 to September 1, 1941, when work was suspended; 529 tons of ore yielded 157 ounces of gold and 45 ounces of silver.

Oroville district.—Yuba Consolidated Gold Fields (Butte Unit) operated four electric connected-bucket dredges in the Oroville district during 1941; the dredge-bucket equipment per boat was as follows: Eighty-four 9-cubic foot, eighty-nine 9-cubic foot, eighty-seven 9-cubic foot, and seventy-one 6-cubic foot buckets. The Sunmar Dredging Co. operated a dragline dredge, which used a dragline

excavator with a 1½-cubic yard bucket, on the Clark, Cratt and Schwartz, Crowder and Binney, Darby, Darby and Crowder, Leal, and Schwartz and Pedrazzini properties. The Placer Exploration Co. operated two dragline dredges—one employed a dragline excavator with a 5-cubic yard bucket and the other a dragline excavator with a 2½-cubic yard bucket—on several properties in the district, including the Dagorret, California Lands, Inc., and Innis. The Golden Feather Dredging Co. operated a dragline dredge, equipped with a dragline excavator and a 5-cubic yard bucket, on Feather River near Oroville during 1941. Kaufield and Danison worked the Ford property with a nonfloating washing plant to which gravel was delivered with a dragline excavator, using a 1-cubic yard bucket, from October 15 to December 31. Wm. Richter & Sons operated dragline dredges on the Belkriet, Bilkli, Freidel, Helen Whittier, Hume and Coleman, John Alm, Lorrie, Ray Angle, Rottinger, and Wyandotte properties. The Interstate Mines, Inc., and Placer Exploration Co. operated dragline dredges on the Gianella ranch. The Oroville Gold Dredging Co. operated a Yuba connected-bucket dredge, with seventy-two 8½-cubic foot buckets, on the Hazelbusch and T. M. Rogers tracts on Feather River 9 miles southwest of Oroville during 1941. The Lemroh Mining Co. operated a dragline dredge, using a dragline excavator with a 2½-cubic yard bucket; 504,848 cubic yards of gravel yielded 2,739 ounces of gold and 195 ounces of silver. The Lobicasa Co. and the Sunmar Dredging Co. operated dragline dredges on the Peters ranch during 1941. The Placer Development Co. operated a dragline dredge with a dragline excavator having a 2½-cubic yard bucket at Meadows 3 miles south of Oroville. The Gold Hill Dredging Co. operated an electric connected-bucket dredge with seventy-four 9-cubic foot buckets on the Wilton Kister ranch on the east side of Feather River 7 miles south of Oroville.

Yankee Hill district.—Hoefling Bros. worked the Surcease mine and operated the company new flotation-cyanidation mill throughout 1941; most of the resulting concentrates were cyanided. Piombo Bros. & Co. operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, on French Creek from January 1 to December 31.

CALAVERAS COUNTY

Camanche district.—The Gold Hill Dredging Co. operated its electric-connected bucket dredge on the Arlington and Osterman properties along the Mokelumne River from January 1 to May 21, 1941. For 6 months Cat Camp Placers operated a nonfloating washing plant to which gravel was delivered by carry-all; 100,000 cubic yards of gravel yielded 605 ounces of gold and 34 ounces of silver. The Lobicasa Co. operated a dragline dredge, using a dragline excavator with a 3-cubic yard bucket, on the City of Stockton reservoir site from July 1 to December 23, when the ground was worked out. Burson Mining Co. operated a dry-land dredge on the Foster ranch intermittently; 495 ounces of gold and 37 ounces of silver were recovered from 55,200 cubic yards of gravel. From January 1 to July 22 Mehrten Bros. operated a nonfloating washing plant to which gravel was delivered by carry-all; 146 ounces of gold and 15 ounces of silver were recovered from treatment of 16,200 cubic yards of gravel. From January 18 to March 25 the Midas Placer Co. operated a non-

floating washing plant on high-channel gravel at the Penn gold-copper-zinc lode property. E. A. Bacon operated a nonfloating washing plant, to which gravel was delivered by bulldozer and carry-all, at the Wallace mine during 1941.

Campo Seco district.—Glo-Bar Mines operated the Glo-Bar drift mine in 1941. The Ralford Mining Co. operated a dragline dredge, using a dragline excavator with a ⅞-cubic yard bucket, on the Wm. P. Hiatt ranch from February 1 to July 10; 25,000 cubic yards of gravel yielded 199 ounces of gold and 14 ounces of silver.

Copperopolis district.—The Jumbo Consolidated Mining Co. turned over the Mountain King mine to the El Gabilan Corporation during 1941; gold ore was treated by flotation, and the gold concentrates were shipped to a smelter.

East Belt district.—The St. Joseph Lead Co. worked the Sheepranch mine throughout 1941; the ore was treated in a 150-ton amalgamation-flotation mill, and the concentrates were shipped to a smelter. The Horseshoe Dredging Co. operated a dragline dredge on Jesus Maria Creek from July 25 to October 24.

Jenny Lind district.—F. S. Tower operated the Royal mine during 1941; the ore was treated in a 20-stamp mill that employed amalgamation, flotation, and vanner concentration. Thompson Dredge operated a dragline dredge having a dragline excavator with a 2½-cubic yard bucket on the Gregory, Sinclair, and Dickhaut ranches 1½ miles southwest of Jenny Lind from January 1 to April 20; later in the year the dredge was operated in Siskiyou County by the Shasta Dredging Co. C. F. Vanciel operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, at the Hatler mine 5 miles west of Jenny Lind on Calaveras River from February 20 to April 26; 552 ounces of gold and 27 ounces of silver were recovered from 87,848 cubic yards of gravel. G. T. Oien operated a nonfloating washing plant to which gravel was delivered by mechanical means. The Horseshoe Dredging Co. and the Stagan Mining Co. operated dragline dredges on the Robie property on Calaveras River 2 miles southwest of Jenny Lind during 1941. The Stagan Mining Co. also operated its dragline dredge on the Willits ranch from October 15 to December 31; the dragline excavator had a 1¾-cubic yard bucket. Henry & Weaver operated a dragline dredge, using a dragline excavator with a ¾-cubic yard bucket, on Neapolitan Gulch from July 23 to November 7. The Wolhall Dredging Corporation operated a dragline dredge which had a dragline excavator with a 2-cubic yard bucket near Jenny Lind intermittently in 1941.

Mother Lode district.—The Carson Hill Gold Mining Corporation treated 381,326 tons of gold ore at the Carson Hill mine during 1941 and produced amalgamation bullion containing 5,835 ounces of gold and 559 ounces of silver; cyanidation bullion containing 15,390 ounces of gold and 5,141 ounces of silver; and 48 tons of gravity concentrates which, after partial extraction by amalgamation, contained 1,046 ounces of gold, 1,473 ounces of silver, and 590 pounds of copper when delivered to a smelter. According to the company printed annual report for the year ended September 30, 1941, the average recovery was $2.15 per ton of ore compared with $2.19 for the year ended September 30, 1940. Operating costs (including 4,251 feet of development work and maintenance and improvement of plant) were reported as $1.94 per ton compared with $1.90 for the preceding

year. Because of the narrow-profit margin and rising costs, no ore-reserve figures were given. R. Hageman operated the Del A Ray mine from August 15 until the end of the year; 700 tons of ore were treated by amalgamation and concentration, and bullion, containing 200 ounces of gold and 40 ounces of silver, and 11 tons of concentrates, containing 3 ounces of gold, were produced. Le Roi Mines, Inc., worked the Easyz Bird mine and operated its 125-ton flotation mill from February 10 until the end of 1941; most of the gold was recovered by the smelting of concentrates. The Horseshoe Dredging Co. operated a dragline dredge on the Beers, Gertzen, and Osborn ranches. The San Andreas Gold Dredging Co., which was sold to Thurman & Wright March 7, 1941, operated two dragline dredges on the Fischer, Hageman-Huberty, Hageman, Lombardi, and Nuner properties; each dragline excavator had a 1½-cubic yard bucket. The Fire Protection Engineering Co. operated a nonfloating washing plant, to which gravel was delivered by mechanical means. Quartz Hill Placers and A. W. Ellis operated a stationary washing plant, to which gravel was delivered by a power shovel, on the Quartz Hill property; 11,270 cubic yards of gravel yielded 298 ounces of gold and 30 ounces of silver. The Imperial Dredging Co. operated a dragline dredge on the White property from April 1 to September 4.

ELDORADO COUNTY

East Belt district.—The Cosumnes Mines, Inc., treated gold ore from a group of claims in the Grizzly Flat section of the East Belt by amalgamation and concentration in 1941. The Eagle King Mining Co. worked the Eagle King mine; gold ore was treated in a 40-ton flotation mill, and the concentrates were shipped to the Empire Star mill in Grass Valley for cyanidation. The Greenhorn Dredging Co. operated a dragline dredge on the Barkley property near Youngs. W. D. Ingram operated a dragline dredge at Horseshoe Bar on American River from October 7 to December 31; dredging was conducted also in Placer County part of the year, as the river passes through the property and the center of the river is the county line.

Mother Lode district.—The Alhambra-Shumway Mines, Inc., worked the Alhambra mine from January 1 to June 1, 1941; 1,983 tons of ore treated by amalgamation and flotation yielded bullion, containing 799 ounces of gold and 111 ounces of silver, and 17 tons of concentrates containing 123 ounces of gold and 19 ounces of silver. The Madre de Oro Gold Mines, Inc., reopened the Church mine and treated 496 tons of ore in a 3-stamp mill; gold bullion containing 149 ounces of gold and 35 ounces of silver was recovered by amalgamation, and 5 tons of concentrates containing 20 ounces of gold and 5 ounces of silver were recovered by flotation; the company constructed a 20-stamp mill. The California Aztec Mining Co. operated its Kelsey Unit from January 1 to September 24 and treated ore by amalgamation and flotation in a 50-ton mill. The Middle Fork Gold Mining Co. operated the Sliger mine and treated the ore in a 160-ton amalgamation-flotation mill; during 1941 a new changehouse was completed at the property. This company's recent development of a method [1] using tailings for stope filling has proved very successful.

[1] Plumb, C. W., Filling Mine Stopes with Mill Tailings: Min. Cong. Jour., vol. 28, No. 1, January 1942, pp. 12-14.

The El Dorado Dredging Corporation operated a dragline dredge using a dragline excavator with a 1½-cubic yard bucket on Coloma Creek 2 miles south of Greenwood from January 1 to March 6; 833 ounces of gold and 124 ounces of silver were recovered from 106,078 cubic yards of gravel. This company moved its equipment to the Hughes property on Rock Canyon Creek and handled 338,940 yards of gravel, from which 2,630 ounces of gold and 281 ounces of silver were recovered between March 17 and October 28; at the end of the year the dredge operated on Irish Creek. W. D. Ingram operated dragline-dredging equipment on the Craig Osborne, Craig Royce, Craig Salt Water, Emma J. Hodgkin, and Red Raven properties. The General Dredging Corporation operated a dragline dredge with a dragline excavator, using a 2-cubic yard bucket, on ground adjacent to American River near Coloma from January 1 to August 30; the company operated a second dragline dredge, equipped with a dragline excavator having a 1½-cubic yard bucket, in the same area from January 1 to September 30. Van Dyke, Modrell, and Warner operated a dragline dredge, using a dragline excavator with a ¾-cubic yard bucket, on the Emma Gordon property from May 17 to September 10. The Orolomo Co. operated a dry-land dredge, which had a dragline excavator with a 1½-cubic yard bucket, on Indian Creek throughout 1941. The River Pine Mining Co. operated its dragline dredge on the North Fork of Cosumnes River near Nashville between July 8 and December 15; this dredge worked in the East Belt district, Amador County, the first half of the year.

West Belt district.—The General Dredging Corporation moved its smaller dragline dredge from Coloma to a site near Shingle Springs; operations were resumed October 1 and continued until the end of 1941. The Big Canyon Dredge operated a dragline dredge, using a dragline excavator with a 3-cubic yard bucket, on Deer Creek for 11 months; 3,160 ounces of gold and 321 ounces of silver were recovered from 540,000 cubic yards of gravel.

FRESNO COUNTY

Friant district.—Griffith Co. and Bent Co., which supplied gravel for the Friant Dam in 1941, recovered 4,990 ounces of gold and 747 ounces of silver in preparing 3,935,620 tons of sand and gravel. Hopkins & Becker operated a suction dredge invented by Becker on the San Joaquin River near the town of Friant; 298 ounces of gold and 61 ounces of silver were recovered from 121,000 cubic yards of gravel. The dredge had a 6-inch centrifugal gravel pump, gasoline engine, and riffle tables mounted on a steel pontoon hull; the suction point could be lowered vertically 28 feet below water level.

HUMBOLDT COUNTY

Orleans district.—Hydraulicking at the Pearch mine yielded 266 ounces of gold and 38 ounces of silver from 128,500 cubic yards of gravel in 1941.

IMPERIAL COUNTY

Cargo Muchacho district.—The Holmes & Nicholson Mining & Milling Co. shipped substantial quantities of gold ore from the Cargo Muchacho group of claims and the Gold Bird mine to the company

100-ton all-slime-cyanidation mill 4 miles west of Winterhaven in 1941.

Mesquite Diggings district.—The Reese Production Corporation operated an open pit on the property leased from the Desert Gold & Aluminum Co. from March 22 to November 8, 1941; the ore, which was treated by amalgamation, resembled cemented gravel.

INYO COUNTY

Bishop Creek district.—The United States Vanadium Corporation produced a copper concentrate containing a substantial quantity of silver as a byproduct of ore treated primarily for tungsten in 1941.

Chloride Cliff district.—Lessees shipped gold ore from the Old Mill schist mine to a custom cyanide plant in 1941.

Modoc district.—From the Colorado mine E. H. Snyder and associates shipped 416 tons of zinc carbonate ore, containing 327,058 pounds of zinc, to a zinc oxide plant in the San Francisco Bay region and 336 tons of ore to the Combined Metals Reduction Co. flotation plant at Stockton, Utah, during 1941; the zinc concentrates from the material treated at Stockton contained 2 ounces of gold, 529 ounces of silver, 6,715 pounds of copper, and 185,475 pounds of zinc. This property, though still in the prospecting stage, was the largest zinc producer in California during the year.

Resting Springs district.—Shoshone Mines, Inc., shipped ore from the Columbia No. 2 mine throughout 1941 and was by far the largest producer of lead and the sixth-largest producer of silver in the State.

Sherman district.—A substantial quantity of gold was recovered by cyanidation of ore mined by the Arondo Mining Co. at the Arondo mine during 1941. Burton Bros., Inc., operated the Ruth mine and treated 21,181 tons of ore by crushing and cyanide-leaching; 5,587 ounces of gold and 105 ounces of silver were recovered.

South Park district.—Lessees on the Cecil R. mine shipped gold ore to a custom cyanide plant in 1941. Mining Associates shipped gold ore from the Gold Bug mine to custom mills. Several lessees worked the Mint-O-Gold mine and shipped a total of 593 tons of ore to custom cyanide mills; 515 ounces of gold and 25 ounces of silver were recovered. The Old Gold Mines Co. shipped lead ore containing substantial quantities of gold and silver from the Old Gold mine.

Union district.—Lessees on the Reward (Brown Monster) mine shipped 451 tons of ore containing 260 ounces of gold and 1,639 ounces of silver to a custom cyanide plant in 1941.

Wild Rose district.—The Del Norte Mining Co. treated gold ore by cyanidation and concentration at the Del Norte-Skidoo group in the Skidoo section of the Wild Rose district during 1941. L. Warnken cyanided ore at the Tucki mine.

KERN COUNTY

Amalie (Agua Caliente) district.—Lessees operated the Aunt Rosa mine and treated ore by amalgamation and concentration during 1941.

Cove district.—Kern Mines, Inc., operated the Big Blue mine throughout 1941; 43,914 tons of ore yielded amalgamation bullion containing 2,909 ounces of gold and 1,218 ounces of silver and 728 tons of flotation concentrates containing 3,130 ounces of gold, 9,142

ounces of silver, 578 pounds of copper, and 19,748 pounds of lead; the concentrates were shipped to a smelter.

Green Mountain district.—Geringer Bros. operated the Gwynne mine from April 15 to December 10, 1941; gold ore was shipped to a custom cyanide plant. The Lone Star Mining Co. worked the Lone Star mine; most of the ore was treated in the company 10-stamp mill, but a small quantity was shipped to a custom cyanide plant.

Mojave district.—The Cactus Mines Co. operated the Cactus Queen mine in the Middle Butte section of the Mojave district throughout 1941 and treated gold-silver ore in the company 125-ton cyanidation-flotation mill; the resulting concentrates were shipped to a smelter. In 1941, for the fourth year, this property was the State's leading silver producer. The Golden Queen Mining Co. operated the Golden Queen mine the entire year; in addition to treating a large tonnage of company ore in its 425-ton cyanide mill, it did a substantial custom-mill business. The Lodestar Mining Co. and lessees shipped 50,613 tons of gold-silver ore containing 9,177 ounces of gold and 180,875 ounces of silver to custom cyanide mills; mining operations were suspended September 13, the property, machinery, and equipment were sold to the Golden Queen Mining Co., and the corporation was completely liquidated November 30, 1941. The Standard Hill Mines Co. and numerous lessees shipped 7,381 tons of ore from the Standard Hill mine to custom cyanide mills; 2,726 ounces of gold and 33,136 ounces of silver were recovered. Burton Bros., Inc., operated the Tropico mine both on company account and through lessees; 35,494 tons of gold ore treated in the company 150-ton cyanide plant yielded 8,042 ounces of gold and 13,444 ounces of silver. In addition, the company treated over 8,800 tons of custom material from 215 shippers during 1941. As a pioneer in California custom milling east of the Sierra Nevada Mountains, Burton Bros., Inc., has been an important factor in the development of mineral resources within a radius of 100 miles or more of Rosamond, where the company mill is located. Lessees on the Whitmore mine shipped 790 tons of gold-silver ore to custom cyanide mills; 310 ounces of gold and 5,296 ounces of silver were recovered.

Randsburg district.—The Butte Lode Mining Co. operated the Big Butte mine throughout 1941; 727 tons of ore treated by amalgamation yielded 262 ounces of gold and 91 ounces of silver, and current sands from this operation, plus 490 tons of old tailings, yielded 10 ounces of gold and 3 ounces of silver by cyanide leaching. Several groups of lessees worked the Big Dyke mine and shipped 903 tons of ore to custom cyanide plants, which recovered 356 ounces of gold and 37 ounces of silver. J. M. Kreta operated the Big Gold group; the custom cyanide plant to which the ore was shipped recovered gold and silver. Lessees on the Buckboard mine produced 1,563 tons of gold ore during 1941; 970 tons treated by amalgamation at the Baltic mill yielded 228 ounces of gold and 46 ounces of silver, and 593 tons of ore shipped to a custom cyanide plant yielded 182 ounces of gold. Lessees shipped gold ore from the K. C. N. mine to custom cyanide plants. The King Solomon Mines Lease and other lessees worked the King Solomon mine during 1941; 1,915 tons of ore and 1,972 tons of old tailings were treated in a 5-stamp mill and cyanide-leaching plant; the amalgamation bullion contained 852 ounces of gold and 247 ounces of silver, and the cyanidation bullion contained 77 ounces of

gold and 19 ounces of silver; 3 tons of concentrates shipped to a smelter yielded 7 ounces of gold and 35 ounces of silver. Shipments, totaling 674 tons, of gold ore from the Wade mine to a custom cyanide mill yielded 479 ounces of gold. The Anglo American Mining Corporation, Ltd.—largest operator in the Randsburg district—treated 454,583 tons of old tailings and recovered 7,731 ounces of gold and 3,245 ounces of silver during 1941. The old tailings were treated by slime-agitation and sand-leaching in a 1,400-ton cyanide plant; 237,976 pounds of "Aero" brand calcium cyanide were consumed.

LOS ANGELES COUNTY

Cedar district.—The Governor Mine Co., operator of the Governor mine, was the principal producer in the Cedar district during 1941; operations were suspended late in the year.

Neenach district.—A substantial quantity of gold ore was shipped from the Big Susanna mine to a custom cyanide mill during 1941.

MADERA COUNTY

Dennis district.—Two suction dredges were operated in 1941 on Fresno River where it passes through the Cassaurang ranch. H. A. Berg also operated a suction dredge on Fresno River; 22,000 cubic yards of gravel yielded 257 ounces of gold and 74 ounces of silver.

MARIPOSA COUNTY

East Belt district.—The Diltz mine was worked during 1941. The Black Oak Mining Co. operated the Feliciana mine; 716 tons of ore treated by amalgamation and flotation yielded bullion containing 228 ounces of gold and 36 ounces of silver and 6 tons of concentrates containing 59 ounces of gold and 11 ounces of silver; the concentrates were shipped to a smelter. A 25-ton amalgamation-flotation mill was constructed on the Feliciana property and put into operation November 1, 1941.

Hunter Valley district.—The Pacific Mining Co. reopened the Washington and Jenny Lind lode claims in 1941 and put a newly constructed 125-ton flotation mill into operation in July; a substantial quantity of ore was treated, and the resulting concentrates were shipped to a smelter. The Pacific Mining Co placed the operation under a corporation—Lind Mining Co. September 1. The Mount Gaines Mining Co. worked the Mount Gaines mine. Thurman & Wright operated a dragline dredge, equipped with a dragline excavator having a 6-cubic yard bucket, on the Crocker-Huffman Land & Water Co. property from June 17 until the end of 1941. The Barker Corporation operated a dragline dredge on Eldorado Creek and on several other properties, including the Givens, Trabucco, Turner, and Waltz. The Trebor Corporation also carried on dragline dredging on several properties, including the Fretz, Gaskill, Machado, Trabucco, Turner, and Waltz.

Mother Lode district.—The Granite King mine was worked in 1941. The Boston California Mining Co. operated the Malvina group. The Pacific Mining Co. worked the Pine Tree and Josephine mines during the year and treated 58,151 tons of ore by amalgamation and

flotation; the amalgamation bullion contained 1,465 ounces of gold and 313 ounces of silver, and the flotation concentrates shipped to a smelter contained 7,507 ounces of gold, 1,802 ounces of silver, and 2,770 pounds of copper. This company also produced a small quantity of gold at the Evans and French properties. Golden Quail, Inc., treated 4,200 tons of ore from the Quail mine in a 50-ton amalgamation-flotation mill; amalgamation bullion contained 57 ounces of gold and 10 ounces of silver, and 49 tons of concentrates shipped to a smelter contained 217 ounces of gold, 151 ounces of silver, and 103 pounds of copper. The Golden Quail, Inc., lease was returned to the Quail Mining Co. in December, 1941. The Barker Corporation did dragline dredging on the Adams, Explorers, Inc., Munn, Penrose, R. Williams, and Stratton properties.

MERCED COUNTY

Hunter Valley district.—The Thurman & Wright dragline-dredge operations on the Crocker-Huffman Land & Water Co. and Waltz properties extended from Mariposa County into Merced County during part of 1941.

Snelling district.—The Merced Dredging Co. operated an electric connected-bucket dredge, with sixty-two 10-cubic foot buckets, one-half mile southeast of Snelling. The electric connected-bucket dredge of Yuba Consolidated Gold Fields (Merced Unit), equipped with seventy-two 9-cubic foot buckets, completely worked out its property 4 miles east of Snelling by the end of 1941. The San Joaquin Mining Co. operated a connected-bucket dredge, with sixty-four 10 cubic foot buckets, 2½ miles southwest of Snelling. The Snelling Gold Dredging Co. operated two connected-bucket dredges on Merced River between Snelling and Merced Falls throughout 1941; one of the dredges was equipped with sixty-six and the other with seventy-two 7-cubic foot buckets.

MONO COUNTY

Blind Springs district.—The Mineral Reduction Co. continued to operate its custom cyanide-flotation mill throughout 1941; 65 shippers sent the plant over 1,400 tons of ore during the year. The decline in precious-metal mining in the area tributary to the mill resulted in plans being made to convert it to producing other concentrates.

Bodie district.—The Roseklip Mines Co. cyanided ore from dumps and open-cuts at the Standard mine in a 400-ton cyanide plant during 1941.

Chidago district.—R. G. Jones operated the Gold Crown mine from January 1 to August 16, 1941; the lease was relinquished August 29, and operations were continued by the owner until the end of the year. The ore was shipped to a custom cyanide mill.

Homer (May Lundy) district.—The Log Cabin Mines Co. operated the Log Cabin (Simpson) mine from January 1 to November 1, 1941; 17,855 tons of ore treated in a 100-ton amalgamation mill yielded 3,287 ounces of gold and 907 ounces of silver.

Mammoth Lakes district.—The Monte Christo Mining Co. operated the Monte Christo group from May 1 to November 1, 1941; a 30-ton flotation mill was built during the year.

NAPA COUNTY

Calistoga district.—The Grigsby (Palisade) mine, worked by the Graham Loftus Oil Corporation in 1940, was operated from January 1 to August 16, 1941, by Helena Consolidated Mines, Inc.; 6,599 tons of gold-silver ore were treated in a 100-ton flotation mill, and 116 tons of resulting gold-silver concentrates containing 350 ounces of gold, 36,121 ounces of silver, and 4,009 pounds of copper were shipped to a smelter. The company reported that the mine was closed August 16, the equipment and buildings had been removed from the property, and no further operations were contemplated.

NEVADA COUNTY

Grass Valley-Nevada City district.—A. Louiselli operated the Black Prince mine during 1941. Grass Valley Bullion Mines, Inc., shipped ore to the Idaho Maryland Mines Corporation mill from January 1 to April 30, after which operations were greatly curtailed. The Empire Star Mines Co., Ltd., operated the Empire, North Star, and Pennsylvania mines at Grass Valley, and the Pennsylvania and Dannebrog at Browns Valley in Yuba County; some work was also carried on at the Zeibright mine in Bear Valley and at the Murchie mine at Nevada City. Late in 1941 work was begun on a drainage, exploration, and tailings-disposal adit from the South Fork of Yuba River near Omega to the lower workings of the Zeibright mine, a distance of over 3 miles. Failure of the extensive exploration campaign in the Murchie mine to reveal substantial quantities of ore resulted in the suspension of all work at the property late in the year. Cooley Butler operated the Golden Center mine. The Idaho Maryland Mines Corporation operated the Idaho Maryland-Brunswick group. According to the company printed annual report for the year ended December 31, 1941, 113,973 ounces of gold and 30,000 ounces of silver were recovered from 263,768 tons of ore, compared with a recovery of 129,309 ounces of gold from 406,707 tons of ore in 1940. Although these figures represent an 11-percent decline in quantity of gold produced, they show a 36-percent gain in grade of ore mined. In 1941, 48,803 tons of ore were derived from development headings, and 214,965 tons were produced by stoping. In addition to company ore, 8,586 tons of custom ore and 348 tons of custom concentrates were treated. Dividends declared and paid in 1941 totaled $1,074,-020.80, raising total disbursements in dividends to $6,797,986.40. The annual report attributes the decline in production in 1941 in part to a 19-day labor strike in May, after which the company had difficulty in rebuilding and maintaining a complete labor force owing to competition from war industries. In addition, unanticipated delays in erecting a new headframe at the New Brunswick shaft, due to a shortage of steel erectors, contributed to the reduction in ore production. The Idaho Maryland-Brunswick operation continued to hold first place among California mines as a gold producer, and the Idaho Maryland Mines Corporation was second to Yuba Consolidated Gold Fields among California gold-producing companies. The Lava Cap Gold Mining Corporation operated the Lava Cap mine throughout the year; 146,900 tons of ore were treated by amalgamation, flotation, and cyanidation in the company 400-ton flotation plant, 25-ton concentrate- and middling-cyanide plant, and 350-ton tailings-cyanide

plant. Cyanidation of sand, slimes, and 4,762 tons of concentrates yielded 1,729 ounces of gold and 19,596 ounces of silver; amalgamation of high-grade ore yielded 318 ounces of gold and 78 ounces of silver; 1,010 tons of flotation concentrates shipped to a smelter contained 36,796 ounces of gold, 324,162 ounces of silver, 38,367 pounds of copper, and 10,737 pounds of lead. Operators of the Queen Lil mine treated 312 tons of ore by amalgamation and recovered 249 ounces of gold and 41 ounces of silver. The Spring Hill Gold Mines, Inc., operated the Spring Hill mine throughout 1941; ore was treated in the company 100-ton flotation plant, and the resulting concentrates were treated by amalgamation and cyanidation. The Stockton Hill Corporation worked the Stockton Hill mine. William Richter & Sons operated a dragline dredge on the Donnelly and Johnson property during 1941. The M. K. Gibson Mining Co. operated a dragline dredge on the Elder, Martel, Neirzert, and Thomas properties. The Wyandotte Dredging Co. operated a dragline dredge with a dragline excavator having a 2½-cubic yard bucket on the Perrin and Pingree properties during 1941; 130,000 cubic yards of gravel treated on the Perrin property yielded 1,186 ounces of gold and 155 ounces of silver, and 70,000 cubic yards washed at the Pingree property yielded 339 ounces of gold and 58 ounces of silver.

North Bloomfield district.—Kaufield & Danison operated a dragline dredge on Columbia Hill from March 1 to April 20, 1941. A B. Innis operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, at the Malakoff mine from October 16 to December 31; 72,000 cubic yards of gravel yielded 333 ounces of gold and 33 ounces of silver. Western Gold, Inc., carried on hydraulicking operations at Relief Hill.

Washington district.—The Omega Co. began hydraulicking March 9, 1941, at the Omega mine upon completion of the Upper Narrows Debris Dam at Smartville and continued operations until July 7; the company washed 429,637 cubic yards of gravel, which yielded 1,302 ounces of gold and 49 ounces of silver. This was the first major operation to take advantage of the debris storage back of the new dam.

ORANGE COUNTY

Santa Rosa district.—The Blue Light Silver Mines, Inc., worked the Silverado or Blue Light mine in Silverado Canyon throughout 1941; the gross content of the concentrates from 403 tons of ore treated by flotation was 18 ounces of gold, 4,846 ounces of silver, 1,300 pounds of copper, 14,383 pounds of lead, and 43,839 pounds of zinc.

PLACER COUNTY

Dutch Flat district.—The Canyon Mines Corporation suspended operations at the Rawhide mine during 1941. La Kamp Bros. operated a nonfloating washing plant at the Mutual mine, to which gravel was delivered with a bulldozer.

Foresthill district.—The Volcano Mining Co., Ltd., worked the Volcano drift mine throughout 1941; 4,000 tons of gravel yielded 206 ounces of gold and 27 ounces of silver.

Iowa Hill district.—The Lebanon Consolidated Mines worked the Occidental drift mine from January 1 until December 31; 3,766 cubic yards of gravel yielded 536 ounces of gold and 63 ounces of silver.

Lincoln district.—A nonfloating washing plant to which gravel was delivered by mechanical means operated on the Guilford ranch during 1941. On the Johnson ranch, C. N. Chittenden operated a nonfloating washing plant to which gravel was delivered by a dragline excavator with a ¾-cubic yard bucket; 43,500 cubic yards of gravel yielded 282 ounces of gold and 51 ounces of silver.

Michigan Bluff district.—The W. D. Ingram dragline-dredge operation on Horseshoe Bar on the Eldorado County line treated some gravel in Placer County.

Ophir district.—The Alabama California Gold Mines Co. operated the Alabama mine throughout 1941; the ore was treated by amalgamation and flotation, and the resulting concentrates were shipped to a smelter; amalgamation bullion contained 14,566 ounces of gold and 4,581 ounces of silver, and 797 tons of concentrates contained 3,527 ounces of gold, 44,862 ounces of silver, 12,045 pounds of copper, and 46,591 pounds of lead. J. K. Wright and L. W. Smith worked the Duncan Hill mine from April 15 to December 31; 200 tons of ore yielded 207 ounces of gold and 85 ounces of silver by amalgamation. Highway Forty Mines, Inc., operated the Highway Forty mine during 1941. V. J. DeCampos worked the Mary Len mine; 1,838 tons of ore treated by amalgamation and flotation yielded 509 ounces of gold and 244 ounces of silver, and 20 tons of concentrates, treated at a custom cyanide plant, yielded 96 ounces of gold and 90 ounces of silver. Oro Fino Consolidated Mines operated the Oro Fino mine during 1941; the ore was treated in an amalgamation-flotation mill, and the resulting concentrates were shipped to a custom cyanide plant and to a smelter. From March to October, on the Ferrari property, the Panob Gold Dredging Co. operated a nonfloating washing plant, with Ainlay bowls, to which gravel was delivered by a dragline excavator with a 1½-cubic yard bucket; the same company operated similar equipment on the Forsyth & Lewis property. H. W. McKinley operated a dragline dredge on the Fisher ranch from June 17 to July 31. Gold Placers, Inc., operated a dragline dredge on the Robinson ranch from April 30 to August 30 and on the Leak ranch from September 7 to December 20. Hallstrom and Lindblad operated during 1941 a nonfloating washing plant, to which gravel was delivered by mechanical means, on the Joseph Mooney, Mathilda Bahr, and Rogers ranches and in Miners Ravine. The Roseville Gold Dredging Co. operated a connected-bucket dredge, with seventy-two 3-cubic foot buckets, in Strap Ravine 6 miles east of Roseville. The Gold Recoveries Corporation operated a dragline dredge on the William Ayers and Anderson properties.

PLUMAS COUNTY

Genesee district.—The Walker Mining Co. (affiliate of the Anaconda Copper Mining Co.) suspended operations October 31, 1941, at its Walker mine, the outstanding mine in Plumas County and California's largest copper producer for several years. According to the company printed annual report for the year ended December 31, 1941, 291,438 tons of ore were milled and 14,387 tons of concentrates produced. Shipments comprised 14,929 tons of concentrates, lime scale, and precipitates, with a net recoverable content of 7,248,128 pounds of copper, 10,938 ounces of gold, and 166,581 ounces of silver. The

company report states that, despite a vigorous exploration campaign for more than 2 years, ore developments had been unfavorable and the operation remained unprofitable under the prevailing prices for copper.

Greenville (Crescent Mills) district.—Cherokee Mine operated the Cherokee mine throughout 1941; 26,344 tons of ore were treated in the company 150-ton cyanidation-flotation mill, and 127 tons of resulting concentrates were shipped to a custom cyanide plant. In all, 5,627 ounces of gold and 1,726 ounces of silver were recovered.

Johnsville district.—In 1941 lessees and sublessees on the Jamison mine treated 489 tons of ore and 401 tons of old tailings by amalgamation and concentration and shipped 112 tons of ore and 3 tons of concentrates to a smelter; amalgamation bullion contained 103 ounces of gold and 13 ounces of silver; ore smelted contained 144 ounces of gold and 38 ounces of silver; and concentrates smelted contained 11 ounces of gold and 3 ounces of silver. The Lobicasa Co. operated a dragline dredge on Jamison Creek from August 20 to December 24.

Lights Canyon district.—A. B. Innis operated a dragline dredge, equipped with a dragline excavator having a 1½-cubic yard bucket, on Lights Creek from January 1 to September 22, 1941; 1,653 ounces of gold and 130 ounces of silver were recovered from 250,000 cubic yards of gravel.

Quincy district.—Baker and McCowan operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, in Meadow Valley during 1941.

Rich Bar district.—The Virgilia Mining Corporation operated the Ohio Point mine during 1941; the ore was treated in the company 240-ton flotation mill, and the concentrates were shipped to a smelter.

RIVERSIDE COUNTY

Dale district.—D. M. Campbell and sublessees shipped 344 tons of ore from the Los Angeles mine to a custom cyanide plant in 1941; 257 ounces of gold and 3 ounces of silver were recovered. Gold ore from the Mission mine was shipped to the Gold Crown custom cyanide plant.

Eagle Mountain district.—Imperial Metals, Inc., suspended operations at the Black Eagle mine early in 1941; substantial shipments of argentiferous lead ore were made to a smelter.

SACRAMENTO COUNTY

Cosumnes River district.—Hoosier Gulch Placers operated boat No. 1 on the Biggs ranch and boat No. 2 on the Rossi property throughout 1941. Cosumnes Gold Dredging Co. operated an electric connected-bucket dredge with sixty-three 12-cubic foot buckets 7 miles southwest of Sloughhouse. McQueen & Downing operated a dragline dredge on Deer Creek from January 1 to February 14. The Humphreys Gold Corporation operated a nonfloating washing plant, which was converted to a dragline dredge, on the Fassett-Parker-Hanlon and Hutchinson properties. F. O. Bohnett also operated on the Hutchinson property. At the end of 1941 the Humphreys Gold Corporation equipment consisted of five dragline excavators, each with a 2½-cubic yard bucket—three for stripping and two for delivering gravel to two washing plants. An average of 18 feet of over-

burden was side-cast, and 12 feet of gravel and 1 foot of bedrock were washed. The Lobicasa Co. operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, on the Mahon property from June 5 to October 17 when the property was worked out.

Folsom district.—The Capital Dredging Co. operated two electric connected-bucket dredges on its property 5 miles south of Folsom during 1941; one dredge had 88 and the other 100 18-cubic foot buckets. The General Dredging Corporation—dissolved September 30, 1941, and continued as General Dredging Co., a partnership—operated its dragline dredge No. 1, equipped with a dragline excavator having a 5-cubic yard bucket, at its property on American River. Its No. 2 dredge, operating on the ancient river channel in the same district, used a dragline excavator with a 2-cubic yard bucket; dredge No. 4, working gravel along American River, near Fair Oaks, likewise used a dragline excavator with a 2-cubic yard bucket. The Climax Dredging Co. operated a dragline dredge on the J. Vincent property from January 1 to April 8. The Lancha Plana Gold Dredging Co. operated a Yuba electric dredge with 84 6-cubic foot buckets at Sailor's Bar on American River throughout 1941. The Natomas Co. fleet of seven electric connected-bucket dredges produced more placer gold than any other operation in the State in 1941. The number and size of buckets per dredge were: No. 1, 62 16-cubic foot buckets; No. 4, 67 15-cubic foot; No. 5, 105 12-cubic foot; No. 6, 106 11-cubic foot; No. 7, 98 9-cubic foot; No. 8, 105 12-cubic foot; and No. 10, 83 15-cubic foot buckets. The Carson Creek Dredging Co., Ltd., worked a dragline dredge on the Quinn ranch from January 1 until February 5, when the operation was taken over by the Northwest Development Co.

SAN BERNARDINO COUNTY

Black Hawk district.—A small quantity of gold ore was shipped to custom mills from the Santa Fe (Arlington) mine during 1941; the Beverly Oil Co. foreclosed and acquired title to the property November 21.

Buckeye district.—F. W. Royer shipped gold ore from the Bagdad Chase-Roosevelt group to a smelter during 1941.

Calico district.—Operators of cyanide-leaching plants on Calico tailings were the principal producers in the Calico district in 1941.

Dale district.—The Gold Crown Mining Co., Ltd., worked the Gold Crown mine throughout 1941; in addition to treating company ore, the mill handled over 2,400 tons of custom material from 24 shippers in its 50-ton all-slime cyanide plant. L. A. Wilson shipped 865 tons of ore to a custom cyanide plant; 709 ounces of gold were recovered.

Hart district.—W. W. Hartman operated the Valley View mine from January 1 to August 2, 1941; a substantial quantity of gold ore was treated in the company 40-ton cyanide plant; the mill was used late in the year to test ores trucked from a mine in the Ivanpah Mountains.

Holcomb Valley district.—The Big Bear Mines, Ltd., Inc., operated the Big Bear (Lucky Baldwin) mine from September 5, 1941, until the end of the year; a 150-ton amalgamation-flotation mill was built at the property. The Holcomb Valley Placer Co. operated a non-

floating washing plant, to which gravel was delivered by tractor and scraper, from July 7 to November 16; 16,265 cubic yards of gravel yielded 204 ounces of gold and 10 ounces of silver.

Ivanpah district.—W. F. Houston operated the Carbonate King mine from January 7 to December 31, 1941; 547 tons of ore shipped to a zinc smelter and a zinc oxide plant contained 446,786 pounds of zinc and 1,136 pounds of lead. This operation was the second-largest in zinc output in the State.

Randsburg district.—F. W. Royer operated the Kelly mine largely through lessees during 1941; in addition to Kelly ore, a custom cyanide plant at the mine treated over 6,200 tons of ore from approximately 66 shippers during the year.

SAN DIEGO COUNTY

Pine Valley district.—Long Valley Mining & Milling Association operated the Eagle Nest mine throughout 1941; 767 tons of ore treated by amalgamation and flotation yielded amalgamation bullion containing 73 ounces of gold and 8 ounces of silver, and 8 tons of concentrates shipped to a smelter contained 110 ounces of gold and 14 ounces of silver. During the year construction of a 75-ton amalgamation-concentration mill was begun. This property and several others in the district are recent discoveries.

SAN JOAQUIN COUNTY

Camanche district.—The Gold Hill Dredging Co. operated two electric connected-bucket dredges on the Jennie Lucas, Alex Perie, Putnam, Thorne, and Osterman properties during 1941; one dredge had sixty-six 7¾-cubic foot buckets and the other eighty-seven 8½-cubic foot buckets.

Jenny Lind (Bellota, Linden) district.—The California Gold Dredging Co. operated an electric connected-bucket dredge with eighty-one 6-cubic foot buckets from January 1 to December 11, 1941. The Smith-Notterman Co. operated a dragline dredge, using a dragline excavator with a 1¾-cubic yard bucket, on the Elmer Cady and Lewallen ranches. A. G. Watkins & Sons operated a dragline dredge, equipped with a dragline excavator having a 2-cubic yard bucket, intermittently during 1941 on Calaveras River.

SHASTA COUNTY

Flat Creek (Iron Mountain) district.—The Mountain Copper Co., Ltd., largest mineral producer in Shasta County, worked the Iron Mountain mine throughout 1941. Most of the ore was mined by the open-cut method and was cyanided in a 500-ton sand-leaching plant and 200-ton flotation-countercurrent-decantation plant; in addition, a small shipment of copper ore was made to a smelter.

French Gulch district.—Operators of the Brunswick mine treated 2,009 tons of ore by amalgamation and flotation; amalgamation bullion contained 186 ounces of gold and 28 ounces of silver, and 38 tons of resulting concentrates shipped to a smelter contained 79 ounces of gold and 9 ounces of silver. The Willow Creek Mines, Inc., which had reopened the Greenhorn mine in 1939, abandoned the operation during 1941 and removed much of the equipment to the Bullion dis-

trict in Lander County, Nev. The St. Jude Mining Co. operated the St. Jude mine. The J. H. Scott Co. operated the Washington mine throughout 1941; ore was treated in the company 50-ton amalgamation-flotation plant; all jig concentrates were amalgamated before shipment to a smelter, and part of the flotation concentrates were cyanided and part shipped to a smelter. The French Gulch Dredging Co. operated an electric dredge with seventy-six 4½-cubic foot buckets on Clear Creek.

Igo district.—J. P. Brennan operated a dragline dredge, equipped with a dragline excavator and a ¾-cubic yard bucket, on Champion Gulch from January to June 1941. The Clear Creek Dredging Co. operated two dragline dredges; one dragline excavator had a 1½-cubic yard bucket and the other a 2½-cubic yard bucket. The Crow Creek Dredging Co. operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket; 220,000 cubic yards of gravel were washed. R. S. Olson operated a dragline dredge on Daly Gulch, and C. E. Gruwell operated a dragline dredge on the Fish, Forschler, Rais, and Russell ranches during 1941. The Tehama Dredging Co. operated a dragline dredge, which had a dragline excavator with a ¾-cubic yard bucket, at the Gold Acres mine from March 20 to June 30; 242 ounces of gold and 17 ounces of silver were recovered from 48,860 cubic yards of gravel. The San Gruco Co. operated a dragline dredge on the Happy Valley Land and Water Co. property during 1941. The Dobbin Gulch Dredging Co. operated a dragline dredge, using a dragline excavator with a 1¼-cubic yard bucket, on the Montgomery property on Flat Creek from January 1 to May 30; washing 142,160 cubic yards of gravel yielded 853 ounces of gold and 62 ounces of silver. The B. H. K. Mines operated a dragline dredge, equipped with a dragline excavator having a 1¼-cubic yard bucket, on the R. C. Connelly and Robert Litsch properties on Clear Creek from November 15 to December 31; 54,400 cubic yards of gravel yielded 339 ounces of gold and 48 ounces of silver. The Thurman Gold Dredging Co. operated a Yuba electric dredge of the connected-bucket type, with seventy-two 9-cubic foot buckets, on Clear Creek during 1941.

North Cow Creek district.—DeKarr & Herbert operated a dragline dredge, using a dragline excavator with a ¾-cubic yard bucket, on the Fred Kohle property on North Cow Creek from January 16 to March 17, 1941; 297 ounces of gold and 46 ounces of silver were recovered from 23,800 cubic yards of gravel.

Redding district.—The Carino Hewer Lease operated throughout 1941 the Blue Gravel mine owned by the City of Redding; ore was treated by amalgamation and flotation, and the resulting concentrates were shipped to a custom cyanide plant. The Columbia Construction Co., Inc., recovered 2,810 ounces of gold and 301 ounces of silver in preparing 4,038,167 tons of gravel for use in constructing Shasta Dam; two dragline excavators, one with a 5-cubic yard bucket and the other with an 8-cubic yard bucket, were used in delivering gravel to the washing plant.

Shasta district.—A. G. Cadogon leased the Yankee Jack mine in 1941 and treated the ore by amalgamation and flotation; the resulting concentrates were shipped to a smelter.

SIERRA COUNTY

Alleghany district.—The Dickey Exploration Co. operated the Oriental mine throughout 1941; ore was treated by amalgamation and flotation, and the concentrates were shipped to a smelter. The Original Sixteen to One Mine, Inc., largest gold producer in Sierra County, continued to operate its Original Sixteen to One mine; ore was treated by amalgamation and flotation, and the concentrates were shipped to a smelter. In addition, a lessee cyanided a small quantity of old tailings at the property.

Downieville district.—William Richter & Sons operated a dragline dredge in the bed of Yuba River from June 1 to December 31, 1941; 280,000 cubic yards of gravel yielded 1,403 ounces of gold and 179 ounces of silver. C. L. Best operated the Ruby drift mine—by far the largest drift operation in the State—on Rock Creek 3½ miles southeast of Goodyears Bar.

Pike (Slate Range) district.—A lessee operated the Alaska mine throughout 1941; gold ore was treated in a 60-ton, 20-stamp amalgamation-concentration mill; bullion and lead concentrates were shipped. W. C. Ennis worked the Bowman mine and treated 6,300 tons of ore in an amalgamation mill; the bullion contained 644 ounces of gold and 108 ounces of silver.

Poker Flat (Table Rock) district.—The Loftus Blue Lead Mining Co. hydraulicked in the district during 1941.

Port Wine district.—Poverty Hill Properties began to install a connected-bucket dredge with eighty-two 6-cubic foot buckets on May 13, 1941; production began August 21 and continued until the end of the year. This use of a connected-bucket dredge on a high Neocene channel represents a new departure in placer mining in the State.

SISKIYOU COUNTY

Callahan district.—The Etna Gold Dredging Co. operated a connected-bucket dredge, with 3-cubic foot buckets, from January 1 to August 19, 1941. Okoro Mines, Inc., operated a dragline dredge, using a dragline excavator with a 2½-cubic yard bucket, from July 11 to December 31, and recovered 771 ounces of gold and 101 ounces of silver from 245,000 cubic yards of gravel; in addition, a small quantity of gravel at the property was treated by small-scale hand methods. Oro Trinity Dredging Co. operated a dragline dredge, which had a dragline excavator with a 1½-cubic yard bucket, on Scott River from January 1 to May 31. Yuba Consolidated Gold Fields (Siskiyou Unit) operated a connected-bucket dredge, with seventy-two 9-cubic foot buckets, on Scott River throughout 1941.

Deadwood district.—The C. & E. Dredging Co. operated a dragline dredge, using a dragline excavator with a 2-cubic yard bucket, on McAdams and Cherry Creeks from May 9 to December 31, 1941.

Greenhorn district.—The Schroeder Mining & Development Co. operated the Schroeder mine during 1941. The Lincoln Gold Dredging Co. operated a dragline dredge, equipped with a dragline excavator having a 1¼-cubic yard bucket, on the Calkins property 1 mile east of Yreka from July 7 to December 2; 556 ounces of gold and 78 ounces of silver were recovered from 93,742 cubic yards of gravel; in addition,

E. A. Kinkle recovered a small quantity of gold by using a dry-land plant. The same two operators also worked the Rose property.

Humbug district.—Von der Hellen & Webber operated a dragline dredge, which had a dragline excavator with a 2-cubic yard bucket, on Humbug Creek from January 1 to October 1, 1941.

Klamath River district.—Merriam Mining Merger worked the Buzzard Hill mine from May 20 to December 31, 1941; gold ore was crushed to minus-¼-inch and given a cyanide leach. The Northern Dredging Co. operated a dragline dredge on the Allen and the Collins properties from January to May, when the company was dissolved; the company dragline excavator used a 2-cubic yard bucket. The Thompson Dredge, which changed its name to Shasta Dredging Co. November 27, 1941, operated its dragline dredge on Brasswire Gulch 1 mile southwest of Hornbrook from May 12 to August 16, after moving the equipment from the Jenny Lind district in Calaveras County; the dragline excavator used a 2½-cubic yard bucket. Larson Bros. & Harms Bros. operated three dragline dredges throughout 1941; two of the dragline excavators used 5-cubic yard buckets and the other a 3-cubic yard bucket. The William von der Hellen Mining Co. operated a dragline dredge with a dragline excavator, using a 2½-cubic yard bucket; 6,113 ounces of gold and 928 ounces of silver were recovered from 773,700 cubic yards of gravel. McQueen & Downing operated a dragline dredge on the Neville and Silva properties. H. Bauman operated a nonfloating washing plant, to which gravel was delivered by mechanical means, on the Surveyor's Mistake mine on Vesa Creek during 1941. The Yreka Gold Dredging Co. operated a connected-bucket dredge with sixty-seven 6-cubic foot buckets in Seiad Valley.

Liberty district.—Lessees hydraulicked 27,900 cubic yards of gravel at the Joubert mine and recovered 385 ounces of gold and 58 ounces of silver in 1941. The Midland Co., Inc., operated a dragline dredge, which had a dragline excavator with a 1½-cubic yard bucket, on the North Fork of Salmon River throughout the year; 1,950 ounces of gold and 284 ounces of silver were recovered from 350,000 cubic yards of gravel.

Quartz Valley (Oro Fino, Indian Creek) district.—The Beaver Dredging Co. worked a dragline dredge, using a dragline excavator with a 5-cubic yard bucket, on Indian Creek 6 miles west of Fort Jones from April 16 to December 31, 1941.

Salmon River district.—The Salmon River Gold Dredging Co. operated a dragline dredge, using a dragline excavator with a 3-cubic yard bucket, on several properties in the Salmon River district during 1941.

Scott Bar district.—The Quartz Hill lode mine was operated in 1941.

STANISLAUS COUNTY

Knights Ferry district.—C. F. Vanciel operated a dragline dredge, employing a dragline excavator with a 1½-cubic yard bucket, on the Anderson, Higginbotham, and Kaasa property from May 13 until December 31, 1941; 2,198 ounces of gold and 179 ounces of silver were recovered from 628,400 cubic yards of gravel. The Placer Properties Co. operated a dragline dredge, using a dragline excavator with a 6-cubic yard bucket, on Stanislaus River 8 miles east of Oakdale throughout 1941.

La Grange district.—The La Grange Gold Dredging Co. operated a connected-bucket dredge with sixty-two 10-cubic foot buckets on Tuolumne River throughout 1941. Yuba Consolidated Gold Fields began operations with a Yuba electric connected-bucket dredge, equipped with sixty-nine 9-cubic foot buckets, on Tuolumne River December 15, 1941. The Tuolumne Gold Dredging Co. operated a connected-bucket dredge with one hundred 12-cubic foot buckets from January 1 to April 13, when the dredge capsized.

TRINITY COUNTY

Hayfork district.—The Cinco Mineros Co. operated a dragline dredge, equipped with a dragline excavator having a 1½-cubic yard bucket, on the Albiez, Crews, Parmenter, Ross, and Trimble properties during 1941. H. S., R. A., and R. I. Smith operated a dragline dredge, using a dragline excavator with a 3-cubic yard bucket, on the High Channel mine for 30 days in August and September, and 300 ounces of gold and 40 ounces of silver were recovered from 100,000 cubic yards of gravel; in addition, a small quantity of gold was recovered at the property by hydraulicking.

Helena (North Fork) district.—The North Fork Placer Mining Co. hydraulicked at the North Fork Placer mine on Hydraulic Hill 1 mile from Helena from January 1 to June 30, 1941; 277 ounces of gold and 30 ounces of silver were recovered from 53,500 cubic yards of gravel.

Junction City district.—G. H. Bergin conducted hydraulicking on Canyon Creek from January 1 to July 15, 1941. The Junction City Mining Co. operated a Yuba electric connected-bucket dredge with seventy-five 10-cubic foot buckets along Trinity River near Junction City. Hydraulicking and dragline dredging by Goldfield Consolidated Mines and the Golden Gravels Mining Co. at the Red Hill mine yielded a substantial quantity of gold.

Lewiston district.—The Lincoln Gold Dredging Co. operated two dragline dredges, one using a dragline excavator with a 2½-cubic yard bucket and the other a 1½-cubic yard bucket, on several properties in the Lewiston district during 1941. The properties and recoveries were: Clark-Jansen, 430 ounces of gold and 67 ounces of silver from 109,139 cubic yards of gravel; Costa, 134 ounces of gold and 9 ounces of silver from 26,432 cubic yards of gravel; Dickerson, 149 ounces of gold and 16 ounces of silver from 65,856 cubic yards of gravel; Fancelli, 141 ounces of gold and 19 ounces of silver from 28,170 cubic yards of gravel; Froloff, 2,453 ounces of gold and 158 ounces of silver from 562,732 cubic yards of gravel; and Phillips, 1,134 ounces of gold and 161 ounces of silver from 194,876 cubic yards of gravel. In addition to the dragline production, smaller quantities of gold and silver were recovered by hydraulicking at the Costa and Phillips properties. Havilah Gravels, Inc., operated a dragline dredge, which had a dragline excavator with a 2-cubic yard bucket, on Eastman Gulch from November 23 to December 31; 338 ounces of gold and 48 ounces of silver were recovered from 7,860 cubic yards of gravel. A nonfloating washing plant operated by J. W. Martin and R. W. Setzer on the same property from January 1 to August 1 recovered 163 ounces of gold and 19 ounces of silver from 20,000 cubic yards of gravel. Lewiston Placers hydraulicked at the Lewiston Placers mine from January 27 to July 1 and December 6 to 31.

Salyer district.—The Swanson Mining Corporation operated a hydraulic property during 1941.

Trinity Center district.—The Carrville Gold Co. operated a Yuba electric connected-bucket dredge with seventy-seven 12-cubic foot buckets on the Carr ranch throughout 1941.

Weaverville district.—O. R. Batham operated a dragline dredge on the Bazet Estate property on the East Fork of Stuarts Fork from August 10, 1941, to the end of the year; 626 ounces of gold and 50 ounces of silver were recovered from 205,550 yards of gravel. Batham also carried on smaller operations on the Hook and Ladder and Nugget Bar properties. J. P. Brennan operated a dragline dredge, using a dragline excavator with a ¾-cubic yard bucket, on Browns Creek from July 17 to December 31. Three dragline-dredge operators worked the Hamilton property. Several operators worked the La Grange mine—the Weaver Dredging Co. operated a dragline dredge from January 1 to May 19 and recovered 976 ounces of gold and 89 ounces of silver from 231,124 cubic yards of gravel; and La Grange Placer Mines, Ltd., hydraulicked 113,100 cubic yards of gravel during operations from January 1 to July 1 and from December 16 to 31, recovering 757 ounces of gold and 84 ounces of silver. The Dobbin Gulch Dredging Co. operated a dragline dredge, equipped with a dragline excavator having a 1¼-cubic yard bucket, on the M. A. Brady property from June 13 to December 24; 926 ounces of gold and 80 ounces of silver were recovered from 213,800 cubic yards of gravel. B. H. K. Mines operated a dragline dredge, which had a dragline excavator with a 1½-cubic yard bucket, on the Rehberger property from January 1 to May 2, the M. K. Brown property from May 3 to July 1, the Scharr property from July 20 to September 12, and the Tye property from September 13 to October 22; all operations were on Little Browns Creek. The treatment of 176,000 cubic yards of gravel at the Rehberger property yielded 751 ounces of gold and 41 ounces of silver; 95,000 cubic yards of gravel on the Brown property yielded 405 ounces of gold and 24 ounces of silver; 81,500 cubic yards of gravel on the Scharr property yielded 349 ounces of gold and 28 ounces of silver; and 55,000 cubic yards of gravel on the Tye property yielded 150 ounces of gold and 10 ounces of silver. W. E. Woodbury hydraulicked 20,000 cubic yards of gravel on the Rex mine east of Weaver Creek during 1941. The Hidden Channel, Tout, and Gasper properties were operated by the Viking Dredging Co. from January 1 to February 28, when the operation and equipment were taken over by the Placer Exploration Co. which continued operations until December 2; the dragline dredge used a dragline excavator with a 2-cubic yard bucket.

TOULUMNE COUNTY

East Belt district.—Densmore Mines operated the Densmore mine during 1941. The La Guria Gold Mining Co. ceased operations at the La Guria mine January 23; the mine, held under lease, was returned to its owner. The Mullin-Hampton Dredging Co. operated a dragline dredge, which had a dragline excavator with a 1½-cubic yard bucket, on the Kaplan (Dondero) mine on Woods Creek 1 mile east of Columbia from January 29 to July 15; 365 ounces of gold and 28 ounces of silver were recovered from 85,000 cubic yards of gravel.

Mother Lode district.—Miller & Clemson operated the Eagle-Shawmut mine throughout 1941; the addition of a large ball mill expanded the mill capacity to 500 tons, and ore was treated by amalgamation and flotation. Gravel from the Menke-Hess property near Chinese Camp was treated in a nonfloating washing plant. E. A. Kent operated two dragline dredges, using dragline excavators with 1¾- and 2½-cubic foot buckets, on the Rosasco, Sanguinetti, and Six Bit properties during 1941.

YUBA COUNTY

Browns Valley district.—The Empire Star Mines Co., Ltd., operated the Pennsylvania and Dannebrog mine during 1941.

Dobbins district.—The Dove Mining Co. operated a nonfloating washing plant on the Rose property during 1941.

Smartville district.—The Williams Bar Dredging Co. operated a connected-bucket dredge with eighty-four 6-cubic foot buckets in the bed of Yuba River near Smartville throughout 1941.

Strawberry Valley district.—The R. & M. Mining Co. operated a dragline dredge, using a dragline excavator with a 1¼-cubic yard bucket, at several properties on Slate Creek in 1941. The properties, recoveries, and time periods were as follows: Corley, 423 ounces of gold and 36 ounces of silver from 134,000 cubic yards of gravel between April 15 and June 21; Ophir, 76 ounces of gold and 7 ounces of silver from 15,000 cubic yards of gravel between June 21 and July 8; and First Chance, 691 ounces of gold and 60 ounces of silver from 99,000 cubic yards of gravel between July 21 and November 27.

Yuba River district.—Yuba Consolidated Gold Fields operated a fleet of six dredges at its property in the Yuba River Basin near Hammonton. All the dredges were equipped with 18-cubic foot buckets and electric power; two had 87 buckets each, two had 100 buckets each, one had 126 buckets, and one had 135 buckets.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN THE CENTRAL STATES

(MINE REPORT)

By A. J. Martin

SUMMARY OUTLINE

The critical character of the need fo. expanding the domestic mine output of copper, lead, and zinc prompted Federal defense agencies to give much attention during 1941 to the Central States region, which in 1940 contributed 45 percent of the total United States mine output of lead, 37 percent of the zinc, and 5 percent of the copper. As a result of the urgent necessity for current information on mine production of copper, lead, and zinc during 1941, the Bureau of Mines inaugurated a series of published monthly estimates showing the mine production of these metals in the United States, including the Central States. Mine production in the Central States under the controlled and ceiling prices prevailing in 1941 did not greatly exceed that of 1940; copper output increased 4 percent, lead 1 percent, and zinc 13 percent.

The silver production of the Central States is that recovered as a byproduct from lead, copper, and zinc-lead ores. No gold was recovered from mines in the Central States in 1941; the 5 ounces produced in 1940 came from a placer prospect.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937-41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052
1940	35.00	[6] .711+	.113	.050	.063
1941	35.00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+ ($20.671835) per fine ounce.
[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938-41: Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in the Central States, 1937–41, in terms of recovered metals

Year	Mines producing	Ore and old tailings (short tons)	Gold		Silver	
			Fine ounces	Value	Fine ounces	Value
1937	283	26,516,112	51 44	$1,800	206,041	$159,374
1938	229	19,037,105			386,210	249,671
1939	251	22,972,151	[1] 4 00	140	315,953	214,465
1940	416	25,532,085	[1] 5.00	175	353,737	251,546
1941	447	28,959,189			448,824	319,164

Year	Copper		Lead		Zinc		Total value
	Pounds	Value	Short tons	Value	Short tons	Value	
1937	95,466,000	$11,551,386	204,885	$24,176,430	244,045	$31,725,850	$67,614,840
1938	93,486 000	9,161,628	158,873	14,616,316	198,721	19,077,216	43,104,831

[1] From placer prospecting

Silver.—Production of silver in the Central States in 1941 totaled 448,824 fine ounces, comprising 367,688 ounces derived from refining lead bullion, slags, and skimmings recovered from Southeastern Missouri lead ores; 60,796 ounces from copper ore from Michigan; and 20,340 ounces from galena concentrates recovered in milling zinc-lead ore and fluorspar from Illinois.

Copper.—The copper output of the Central States in 1941 came from copper ore from Michigan and lead ore from Missouri; no copper ore was shipped from Missouri during the year, and the copper produced (2,800,000 pounds) was derived from the treatment of residues from lead smelting. The output of refined copper in Michigan increased from 90,396,000 pounds in 1940 to 92,880,000 pounds in 1941, and the average recovery per ton of combined rock and sands treated increased from 20.4 to 21.7 pounds.

Lead.—The mine production of recoverable lead in the Central States was 209,362 tons in 1941 compared with 207,587 tons in 1940. Output from Southeastern Missouri was 164,342 tons in 1941—5,551 tons less than in 1940—and that of the Tri-State region (Kansas, Oklahoma, and Southwestern Missouri) was 41,080 tons, an increase of 5,769 tons over 1940. The output from Central Missouri, Arkansas, Illinois, Kentucky, and Wisconsin totaled 3,940 tons in 1941, an increase of 1,557 tons over 1940.

Zinc.—The mine output of recoverable zinc in the Central States in 1941 was 276,006 tons, a 13-percent increase over 1940. The

Tri-State region produced 94 percent of the total in 1941, 95 percent in 1940, and 97 percent in 1939. In 1941 Oklahoma contributed 64 percent and Kansas 28 percent of the Tri-State output compared with 70 and 25 percent, respectively, in 1940. Unsold stocks of Tri-State zinc concentrates totaled 907 tons at the end of 1941 compared with 2,764 tons in 1940. The zinc output from Southeastern Missouri in 1941 (893 tons) was contained in carbonate concentrates and ore carrying zinc, lead, and iron shipped from old dumps. Production of zinc in Illinois rose from 4,818 tons in 1940 to 9,198 tons in 1941 and that in Wisconsin from 5,770 to 6,238 tons; in Kentucky the output dropped from 1,278 to 427 tons and in Arkansas from 440 to 206 tons.

MINE PRODUCTION BY STATES AND REGIONS

Mine production of silver, copper, lead, and zinc in the Central States in 1941, by States, in terms of recovered metals[1]

State	Mines producing	Ore and old tailings (short tons)	Silver	
			Fine ounces	Value
Arkansas	32	3,000		
Illinois	6	[2] 72,598	20,340	$14,464
Kansas	58	3,696,247		
Kentucky	8	[2] 16,340		
Michigan	7	4,282,448	60,796	43,233
Missouri	93	6,792,594	367,688	261,467
Oklahoma	120	13,883,989		
Wisconsin	123	211,973		
	447	28,959,189	448,824	319,164
Total, 1940	416	25,532,085	353,737	251,546

State	Copper		Lead		Zinc		Total value
	Pounds	Value	Short tons	Value	Short tons	Value	
Arkansas			11	$1,254	206	$30,900	$32,154
Illinois			2,376	270,864	9,198	1,379,700	1,665,028
Kansas			14,538	1,657,332	71,403	10,710,450	12,367,782
Kentucky			282	32,148	427	64,050	96,198
Michigan	92,880,000	$10,959,840					11,003,073
Missouri	2,800,000	330,400	165,909	18,913,626	21,932	3,289,800	22,795,293
Oklahoma			25,021	2,852,394	166,602	24,990,300	27,842,694
Wisconsin			1,225	139,650	6,238	935,700	1,075,350
	95,680,000	11,290,240	209,362	23,867,268	276,006	41,400,900	76,877,572
Total, 1940	91,766,000	10,369,558	207,587	20,758,700	244,976	30,866,976	[1] 62,246,955

[1] Grand total value for 1940 includes gold from placer prospecting in Indiana, as follows. 5 fine ounces, valued at $175. No output of gold in 1941. See preceding table.
[2] Excludes lead-bearing material mined with fluorspar and from which some lead was recovered as a byproduct of the mining and milling of the fluorspar.

Mine production of lead and zinc in the Central States in 1941, by regions

Region	Lead [1]		Zinc [2]		Total value
	Short tons	Value	Short tons	Value	
Concentrates:					
Joplin or Tri-State	53,690	$3,597,132	478,403	$23,960,568	$27,557,700
Southeastern Missouri [3]	228,572	15,404,226	5,192	73,202	15,477,428
Upper Mississippi Valley [4]	1,810	121,301	14,893	757,833	879,134
Kentucky-Southern Illinois	3,866	219,064	[5] 14,401	687,270	906,334
Northern Arkansas	10	600	[6] 622	16,132	16,732
	287,948	19,342,323	513,511	25,495,005	44,837,328
Total, 1940	283,045	17,162,573	454,882	18,938,538	36,101,111
Recoverable metal:					
Joplin or Tri-State	41,080	4,683,120	258,837	38,825,550	43,508,670
Southeastern Missouri [7]	164,388	18,740,232	1,100	165,000	18,905,232
Upper Mississippi Valley [4]	1,345	153,330	7,956	1,193,400	1,346,730
Kentucky-Southern Illinois	[8] 2,538	289,332	7,907	1,186,050	1,475,382
Northern Arkansas	[9] 11	1,254	206	30,900	32,154
	209,362	23,867,268	276,006	41,400,900	65,268,168
Total, 1940	207,587	20,758,700	244,976	30,866,976	51,625,676

[1] Includes galena and small quantity of lead carbonate concentrates
[2] Includes sphalerite and relatively small quantity of zinc carbonate and silicate concentrates.
[3] Includes 64 tons of lead concentrates and 472 tons of zinc concentrates from Central Missouri.
[4] Region includes Iowa, Northern Illinois, and Wisconsin; no production in Iowa from 1918 to 1941, inclusive.
[5] Includes 688 tons of zinc-lead concentrates averaging 47.53 percent zinc and 8.14 percent lead.
[6] Includes 81 tons of zinc-lead carbonate ores and concentrates.
[7] Includes 46 tons of lead and 207 tons of zinc from Central Missouri.
[8] Includes 54 tons contained in zinc-lead concentrates.
[9] Includes 5 tons contained in zinc and zinc-lead carbonate ores and concentrates.

The report of this series for 1930 (chapter of Mineral Resources of the United States, 1930, pt. I) gives the areas included in the seven lead- and zinc-producing regions of the Central States. Mineral Resources, 1914, contains brief reviews of the history of lead and zinc mining in the Central States, the yearly production of each State from 1907 to 1914, inclusive, and historical notes and estimates of the total production of lead and zinc in each State before 1907. Subsequent records year by year are found in Mineral Resources and Minerals Yearbook.

Of a total of 477,126 tons of blende concentrates produced in 1941 in the Tri-State region, 74,036 tons—470 tons less than in 1940—were derived from old tailings.

Quantity and tenor of ores.—The quantity and tenor of ores and old tailings treated in Kansas, Michigan, Missouri, Oklahoma, and Wisconsin from 1939 to 1941 are shown in the table that follows. Comparable figures for Kentucky and Illinois cannot be given because the lead and zinc concentrates shipped from some of the mines are recovered as byproducts in the concentration of the fluorspar that they accompany, and the metal content of the crude ore raised cannot be calculated. In Arkansas very little ore was mined annually from 1918 to 1941, and the tenor of most of the ore treated (generally by small mills or hand jigs) was not determined by the operators.

Quantity and tenor of copper, lead, and zinc ores, old tailings, etc., produced in some [1] Central States, 1939–41, by States

State	1939		1940		1941	
	Ore, etc.	Metal content [2]	Ore, etc.	Metal content [2]	Ore, etc.	Metal content [2]
	Short tons	*Percent*	*Short tons*	*Percent*	*Short tons*	*Percent*
Kansas	3,701,300	2.45	3,153,800	2.40	3,696,247	2.55
Michigan	4,603,751	.96	4,438,219	1.02	4,282,448	1.08
Missouri	5,650,800	3.12	6,457,400	2.94	6,792,594	2.85
Oklahoma	8,802,900	2.00	11,250,400	1.80	13,883,989	1.52
Wisconsin	213,400	3.26	190,326	3.61	211,973	3.86
	22,972,151		25,490,145		28,867,251	

[1] Only small-scale intermittent mining done in Arkansas from 1918 to 1941; Kentucky and Illinois excluded because part of the metal output (lead and zinc) was a byproduct of fluorspar mining, and the quantity of metal-bearing material hoisted could not be determined.

[2] The percentages represent metal content of the ore insofar as it is recovered in the concentrates. In Michigan the metal so recovered is copper; in other Central States the metals are lead and zinc combined, relative proportions of which are shown in third table of this chapter and in tables of tenor of ore given in sections devoted to the respective States.

MINING AND METALLURGIC INDUSTRY

Most of the ore mined in the Central States is concentrated by the companies producing it, but that mined by some of the large producing companies in the Tri-State and Upper Mississippi Valley regions is sent to central mills, which also afford an outlet for crude ore produced by individuals and partnerships working small mines or gouging in large mines abandoned by former operators. Gravity concentration continues to be an important factor in the treatment of ores, although flotation is used in nearly all the large mills to supplement the gravity method or as the principal method of treatment. The concentrates generally have an established market. In 1941 copper concentrates from Michigan were smelted at plants at Hubbell and Houghton, Mich.; lead concentrates from Southeastern Missouri were sent to smelters at Herculaneum, Mo., and Alton, Ill.; and lead concentrates from the Tri-State district went to smelters or pigment plants at Galena and Coffeyville, Kans., and Alton and Hillsboro, Ill. Zinc concentrates from the Tri-State district moved to plants at Bartlesville, Blackwell, and Henryetta, Okla.; Coffeyville and Galena, Kans.; Fort Smith and Van Buren, Ark.; Danville, East St. Louis, Hillsboro, and La Salle, Ill.; Donora and Josephtown, Pa.; and Moundsville, W. Va. The lead and zinc concentrates from Wisconsin, Illinois, and other scattered districts in the Central States were shipped to the plants that treated the concentrates from the Southeastern Missouri and Tri-State districts.

REVIEW BY STATES

ARKANSAS

Concentrates and crude smelting ore shipped from lead and zinc mines in Arkansas in 1941 totaled 632 tons containing 11 tons of recoverable lead and 206 tons of zinc compared with 1,570 tons containing 55 tons of lead and 440 tons of zinc in 1940. About 32 small mines and prospects in Boone, Marion, Newton, and Searcy Counties contributed to the output in 1941. Most of the operators hand-jigged or sorted their ore at the mines and sold it in small lots to the Manda Industrial Corporation at Harrison, which reshipped it to smelters or other buyers in carlots. The Hurricane Mining Co. did development work at the Big Hurricane and Excelsior mines in Searcy County and installed a 75-ton mill at the Excelsior near St. Joe; the mill treated about 800 tons of sulfide ore yielding 60 tons of concentrates assaying 58.7 percent zinc. The rest of the concentrates and ore shipped was carbonates or silicates and averaged 37 percent zinc and 2 percent lead. I. A. Lower treated 150 tons of ore and 50 tons of old tailings in the McIntosh mill at Rush, which yielded 20 tons of concentrates. At the Edith mine near Rush the Maricon Mining Co. drove 122 feet of tunnel and a 48-foot drift, did construction work on a 100-ton mill, and shipped 11 tons of sorted crude ore. Other producing mines included the Gloria, Coon Hollow, and Jack Pot in Boone County; Monte Cristo, Red Cloud, and Sure Pop in Marion County; and Lone Star in Searcy County.

ILLINOIS

Northern Illinois (see under Wisconsin for output data).—Gill Brothers operated the old Hughlett and Gray mine in Jo Daviess County from February through December 1941 and shipped 13,639 tons of ore averaging 15.32 percent zinc and 1.03 percent lead to the Vinegar Hill Zinc Co. custom flotation mill at Cuba City, Wis. Operations consisted of robbing pillars, slabbing off sides of old drifts, and taking up bottoms of old stopes. A little zinc ore was cleaned up and shipped from the old Blewett mine in the Galena district.

Southern Illinois.—The Mahoning Mining Co. operated its 200-ton selective flotation mill at Rosiclare continuously in 1941 on zinc-lead fluorspar ore from the company-owned W. L. Davis mine and adjacent leased properties near Cave in Rock. The ore occurs generally in flat-lying or blanket formation with alternating layers, one consisting of fluorspar and the other mostly of sphalerite and galena; it is mined through vertical shafts from open stopes supported by pillars and is transported to the mill by trucks. The commercial products of the mill (in the order recovered) are lead concentrates, zinc concentrates, and fluorspar concentrates (mostly of acid grade). Hillside Fluor Spar Mines continued to ship lead concentrates recovered as a byproduct in the milling of fluorspar, and individuals shipped small lots of lead concentrates from Freeport and Rosiclare. The total output of lead concentrates in Southern Illinois in 1941 was 3,545 tons averaging 64.94 percent lead and 5.74 ounces of silver to the ton, and that of zinc concentrates was 13,292 tons averaging 62.53 percent zinc. Production (in terms of recovered metals) amounted to 2,256 tons of lead, 20,340 ounces of silver, and 7,480 tons of zinc

compared with 1,500 tons of lead, 4,766 ounces of silver, and 4,812 tons of zinc in 1940.

KANSAS

Mine production of lead and zinc increased substantially in Kansas in 1941. The recoverable lead output rose from 11,927 tons in 1940 to 14,538 tons in 1941 and zinc from 57,032 to 71,403 tons. Zinc derived from old tailings decreased from 11 percent of the total in 1940 to 6 percent in 1941. About 58 mines and 18 mills were operated all or part of 1941 compared with 34 mines and 20 mills in 1940. Prices of concentrates and other general details of mining in the Tri-State region are given in the pages of this chapter devoted to Southwestern Missouri.

Mines and mills near Baxter Springs yielded 4,734 tons of lead concentrates and 34,533 tons of zinc concentrates in 1941. The St. Louis Smelting & Refining Co. operated its Ballard mill continuously on ore from the Ballard, Bailey, Clark, English "O", and Shanks mines; the mill output of both lead and zinc concentrates increased materially over 1940. In July 1941 the Bilharz Mining Co. began milling ore from the Bilharz-Brewster mine, at which the company had been conducting a difficult acid-water fight to unwater lower levels and reopen old ground; the company mill also continued to treat ore from the L. D. Brewster mine in Oklahoma. The Madison Mining Co. operated the Peru (old Sunflower) mine and mill steadily. The Lula Bell Mining Co. worked the Opperman mine, treating the ore in the company mill near Hockerville, Okla. Ore from the Robob and Oldham mines was shipped to the Central and Guaranty mills, respectively, in Oklahoma. The Wade custom mill treated 26,222 tons of ore received from small-scale operators in Kansas and Oklahoma.

Production from the Blue Mound-Treece area was 13,939 tons of galena and 87,920 tons of blende. The Eagle-Picher Mining & Smelting Co. operated its Westside-Barr and Webber mines and mills continuously; production of zinc from the Westside-Barr mine showed a large increase over 1940 and was the highest in the Tri-State district for a single mine. The Federal Mining & Smelting Co. ran its Muncie mill on ore from the Muncie-Tar Creek-Semple Group; the ore from the Federal Jarrett mine was sent to the company Gordon central mill in Oklahoma. Kansas Explorations, Inc., operated its Jarrett lease and mill northeast of the Federal Jarrett from January to November. Ore from the Cherokee mine was shipped to the Woodchuck mill in Oklahoma. The Youngman mill handled tailings until July and was then dismantled and moved to the Robinson mine (operated by the Harris Mining Co.), where it was rebuilt for handling mine "dirt" and operated the rest of the year on ore from the Robinson mine, which had been shipping to the Beck mill at Picher, Okla. Ore from the Bendelari, Black Eagle, Big John, Chubb, Wilbur, and Wright mines was shipped to the Central mill at Cardin, Okla. The Dines Mining Co. mill treated company and custom ore, mostly from the Lindsey, Northern, and Southern mines. The New Blue Mound Mining Co., J. A. Worley, and the Pilot Oil Co. also operated mine mills. Operators of tailing mills in Kansas were the Captain Milling Co., C. Y. Semple, and H. D. Youngman.

The Kansas part of the Waco district yielded 15 tons of galena concentrates and 8,361 tons of blende. The St. Louis Smelting & & Refining Co. reopened its No. 9 group of mines and 800-ton mill in April and operated them the rest of the year; some of the ore milled came from the Missouri part of the property The F. W. Evans mill (formerly R. H. & G.) treated ore from leases on the O'Neill land (partly in Kansas and partly in Missouri), the St. Louis Smelting & Refining Co. land, and the Reynolds land. The Peacock mine and mill at the old Badger camp were operated on a small scale from January to September. At Galena, Fred Childress & Sons unwatered the Bailey shaft on the Southside land and shipped some ore late in the year to the Central mill in Oklahoma.

Mine shipments of lead and zinc in Kansas, 1937–41

Year	Mines producing	Lead concentrates		Zinc concentrates		Metal content [1]			
						Lead		Zinc	
		Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1937	42	20,559	$1,454,507	151,646	$6,476,064	16,008	$1,888,944	80,300	$10,439,000

[1] Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates; data on tailing losses not available

KENTUCKY

Shipments of lead and zinc ore and concentrates from Kentucky in 1941 comprised 321 tons of galena averaging 72.27 percent lead, 475 tons of zinc-lead sulfide averaging 54.32 percent zinc and 10.95

percent lead, 616 tons of zinc carbonate averaging 36.2 percent zinc and 1 percent lead, and 18 tons of sphalerite averaging 62.53 percent zinc. The recoverable metal content of the combined concentrates was 282 tons of lead and 427 tons of zinc in 1941, compared with 360 tons of lead and 1,278 tons of zinc, in 1940. The drop in zinc production in 1941 resulted from the closing late in 1940 of the "Hutson" mine and 100-ton mill of the Eagle Fluor Spar Co. near Salem, Livingston County; the only shipments from the mine in 1941 were 55 tons of ore cleaned up from a waste dump. The Twin Valley Mining Co. operated the Gratz mine and mill at Gratz, Owen County, intermittently from May to December and shipped several cars of zinc and lead sulfide concentrates. The United States Coal & Coke Co. Fluorspar Division shipped some zinc-lead and lead concentrates, and the National Fluorspar Co. and the Mineral Ridge Fluor Spar Co. shipped byproduct lead concentrates. A 200-ton lot of ore from Kentucky was sent to the Mahoning mill at Rosiclare, Ill., for experimental milling. Zinc carbonate log-washer concentrates were shipped from the K-K-Mining Co. land near Sheridan and the Blue property near Mexico. The Eagle-Picher Mining & Smelting Co. continued developing its zinc-lead property 6 miles east of Marion.

MICHIGAN

Copper totaling 92,880,000 pounds was produced in Michigan in 1941, an increase of 2,484,000 pounds (3 percent) over 1940. The increase resulted from a rise in the average grade of both mine ore and old tailings treated; the quantity of mine ore milled decreased from 1,827,119 tons in 1940 to 1,741,961 tons in 1941 and that of old tailings from 2,611,100 to 2,540,487 tons.

The adverse effect of rising operating costs on copper production in Michigan under the ceiling price of 12 cents a pound, effective August 6, 1941, was recognized by the Office of Price Administration. In November special arrangements were consummated under which the Procurement Division of the Treasury Department contracted to purchase the copper output of three "high-cost" mines for 6 months at a price per pound equivalent to the "out-of-pocket" cost of production for the 6-month period ended June 30, 1941. The price was adjusted to include a wage increase of $1 a day and expenses incident to the increase, plus an additional cent a pound if the total price a pound is lower than the cost of production during the contract period. Other stipulations provide an incentive for operators to reduce costs and fix maximum prices at 15 and 16 cents a pound. A contract, with similar provisions, for reopening a fourth "high-cost" copper mine in Michigan was executed early in 1942.

The concentrate ("mineral") produced at mills in Michigan in 1941 was smelted at plants of the Calumet and Hecla Consolidated Copper Co. at Hubbell and the Copper Range Co. at Houghton. Copper bullion that carries an amount of silver sufficient to make the separation and recovery of this metal profitable is cast into anodes and shipped to electrolytic refineries outside the State. The quantity of silver recovered from anodes shipped was 60,796 fine ounces in 1941 compared with 88,657 ounces in 1940.

Mine production of gold, silver, and copper in Michigan, 1937–41 [1]

Year	Gold (fine ounces)	Silver (fine ounces)	Copper [2]			Concentrate ("mineral") [3]		Ore ("rock") (short tons) [4]
			Pounds	Yield				
				Pounds per ton of ore ("rock")	Percent	Pounds	Yield (percent copper)

1939	69,154	9,148,880	1.99	9,218,034					

The Calumet and Hecla Consolidated Copper Co. operated the Ahmeek and Peninsula groups on the Kearsarge lode throughout 1941 and in October began working the adjacent Douglass property under a 25-year lease from the Copper Range Co. During the year the company obtained a modification of its lease and option on the Peninsula group under which the term of the lease and option might be extended from year to year after July 1, 1943, upon payment of yearly installments on the purchase price. In July 1941 the company purchased all the lands of the Ojibway Mining Co. at public sale; these comprised 3,000 acres north of and contiguous to the Peninsula property. Development and mining on the Peninsula and Douglass properties were carried on from the Ahmeek mine workings, which are reached through three inclined shafts 7,043, 5,903, and 5,157 feet deep. Development done in 1941 comprised 334 feet of shaft, 10,094 feet of drifts, and 43,942 feet of diamond drilling. The ore produced was treated in the 6,800-ton Ahmeek stamp mill by gravity concentration followed by flotation of the fines. The annual company report to stockholders shows an output of 28,670,000 pounds of copper from mine ore and 32,766,000 pounds from tailings treated in reclamation plants. It was estimated that at the 1941 rate of production the conglomerate tailings will be exhausted in about 2½ years.

Operations at the Calumet and Hecla reclamation plants at Lake Linden and Hubbell in 1941 and for the entire period of their operation

	1941	Since beginning
Quantity treated short tons	2,295,000	38,365,000
Assay headings percent	0.835	0.671
Assay tailings do	.117	.123
Refined copper produced pounds	32,766,000	419,791,000
Refined copper produced per ton treated do	14 28	10 94

The Copper Range Co. operated its Champion and Globe mines and 2,500-ton mill at Freda throughout 1941, except for about 3 weeks following a fire at the mine on November 22; the company tailings-recovery plant was run from April to December, inclusive. The Champion mine is opened by a 70° shaft 5,361 feet deep, through which the workings of both mines are reached. Copper recovered from 304,480 tons of mine ore and 245,487 tons of sands treated totaled 16,677,304 pounds. The average yield of fine copper per ton of mine rock was 52.38 pounds compared with 57.72 pounds in 1940. The concentrates produced in the mills were treated in the company smelter, which also handled custom concentrates from the mills of the Isle Royale Copper Co. and the Quincy Mining Co.

The Isle Royale Copper Co. mine and 2,000-ton stamp mill were run continuously in 1941, except for a shut-down of about a week in September owing to a labor strike at the mine. The quantity of crude ore produced decreased from 391,073 tons in 1940 to 316,598 tons in 1941, owing mainly to a reduction in the output from No. 5 shaft; production from No. 4 shaft nearly equalled that in 1940. Fine copper yielded per ton of rock treated averaged 21.223 pounds in 1941 and 19.897 pounds in 1940.

The Quincy Mining Co. operated its mine and mill steadily in 1941. The tonnage of rock treated and the yield of copper per ton were both slightly lower than in 1940.

MISSOURI

The total value of recoverable silver, copper, lead, and zinc produced from Missouri mines was $22,795,293 in 1941 compared with $19,145,700 in 1940. The silver output in 1941 (367,688 fine ounces valued at $261,467) and the copper (2,800,000 pounds valued at $330,400) were byproducts recovered in smelting and refining lead concentrates from Southeastern Missouri. These two metals occur in such small quantity to the ton of concentrates that no value is attached to them in the sale of the concentrates. The lead output of the State came largely from the Southeastern Missouri region and the zinc mostly from Southwestern Missouri. The Central district of Missouri produced 46 tons of recoverable lead and 207 tons of zinc in 1941; these figures are included with those of Southeastern Missouri in the table that follows.

The total output of lead concentrates in Missouri was 230,746 tons with a recovered lead content of 165,909 tons in 1941 compared with 235,746 and 172,052 tons, respectively, in 1940. The total output of zinc concentrates was 44,982 tons with a recovered zinc content of 21,932 tons compared with 24,539 and 12,703 tons, respectively, in 1940.

Mine production of lead and zinc in Southeastern and Central Missouri, 1937–41

Year	Lead concentrates (galena)		Zinc concentrates (sphalerite)		Metal content [1]			
					Lead		Zinc	
	Short tons	Value [2]	Short tons	Value	Short tons	Value	Short tons	Value
1937	209,937	$14,360,271	24	$720	153,205	$18,078,190	11	$1,430
1938	163,500	9,040,593			118,870	10,936,040		
1939	210,526	12,339,360			153,522	14,431,068		
1940	232,871	14,269,600	[3] 815	20,000	169,908	16,990,800	233	29,358
1941	228,572	15,404,226	[4] 5,192	73,202	164,388	18,740,232	1,100	165,000

[1] In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.
[2] Values given are to a certain extent arbitrary, as part of the lead concentrates are smelted by the producer.
[3] Includes 500 tons of zinc carbonate ore containing 106 tons of recoverable zinc.
[4] Includes 4,720 tons of zinc-lead carbonate concentrates containing 893 tons of recoverable zinc and 172 tons of lead.

[1] Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates; data on tailing losses not available.

Southeastern and Central Missouri.—The disseminated-lead district of Southeastern Missouri—largest lead-producing district in the United States—yielded 164,342 tons of recoverable lead in 1941 compared with 169,893 tons in 1940. The bulk of the production in 1941, as in the past, came from St. Francois County, where the St. Joseph Lead Co. operated four groups of mines and the Bonne Terre, Desloge, Federal, and Leadwood mills with a total daily capacity of 21,100 tons of ore. Treatment is by table concentration followed by flotation. The ore occurs in extensive flat-lying deposits in limestone and is mined from open stopes supported by pillars. Electric-powered mechanical loaders and locomotives are used for loading and underground haulage. Thirteen shafts averaging 440 feet in depth were operated in 1941. Development done comprised 41,585 feet of drifts and 1,240,845 feet of diamond drilling. In Madison County the Mine La Motte mine and 1,000-ton mill of the Mine La Motte Corporation (50 percent owned by the St. Joseph Lead Co.) were run steadily. Two shafts, 116 and 308 feet deep, were operated. Development done totaled 2,884 feet of drifts and 29,468 feet of churn drilling. The Ozark Lead Co. mined on the Fleming tract near Fredericktown from January to July; no further production was made from the property until March 17, 1942, when it was reopened by the Fredericktown Lead Co., which had purchased the Ozark Lead Co. mining lease and the Clark & Hallock mill. Of the 228,508 tons of lead concentrates made in 1941 in Southeastern Missouri, 106,232 tons were flotation concentrates. Local buyers and small-scale operators shipped 346 tons of galena recovered in shallow workings (including barite mines) in Jefferson, St. Francois, and Washington Counties.

The zinc output of Southeastern Missouri in 1941 was contained in zinc-lead carbonate concentrates recovered in log washers and

hand jigs from old dump material on the properties of the Valle Mining Co. north of Bonne Terre and the Tausig Estate 9 miles west of De Soto.

In Central Missouri the Wemhaner Mining Corporation produced 472 tons of 49-percent zinc sulfide concentrates and 6 tons of galena in its 100-ton jig-concentration mill, operated intermittently on ore from the leased open-cut mine on the Monarch Coal & Mineral Co. land in Moniteau County. Otis and E. M. Sullens shipped 58 tons of galena recovered in their 10-ton power jig from ore from an open-cut on the Lowery property near Enon.

Southwestern Missouri.—The method of marketing the mine output in the Tri-State or Joplin lead and zinc region (Southwestern Missouri, Kansas, and Oklahoma) differs from that employed in other parts of the country where miners receive pay for ore upon the basis of the assay content of metal at a certain price per unit f. o. b. smelter and freight charges are deducted from the smelter settlement if not paid in advance or guaranteed by the shipper. In the Tri-State region compensation is paid per ton of concentrates f. o. b. mine bins. In effect, however, this is equivalent to paying for the metal contained, inasmuch as the price per ton is based upon a sliding scale determined by the assay content. The standard for zinc sulfide concentrates is 60 percent zinc and for lead sulfide 80 percent lead. No base prices have been quoted in recent years for zinc silicate and lead carbonate concentrates, as the output has been scattered and small.

The total value given in this report for all concentrates produced in the Tri-State region is based upon actual receipts by the sellers and not upon quoted prices. The quoted price is that paid for medium quantities or carlots; small lots bring less. The quoted weekly price a ton for Tri-State zinc blende concentrates at Joplin from January 1 to September 6, 1941, was $48.00. A slight adjustment upward to $48.58 was made in the next quotation (September 12), and this price held until October 10, when the quotation was raised to $55.28 and remained at this figure the rest of the year. The quoted weekly price for galena concentrates from January 4 to February 8 was $64.54; February 15 to March 1, $66.70; March 8 to 22, $68.14; March 29 to June 28, $69.58; and July 5 to January 3, 1942, $68.64. The average price paid for zinc silicate and carbonate shipped in 1941, most of which was low-grade, was $11.24 a ton.

Production of zinc concentrates in the Tri-State region increased from 429,778 tons valued at $18,062,867 in 1940 to 478,403 tons valued at $23,960,568 in 1941, and that of lead concentrates from 46,212 tons valued at $2,724,795 to 53,690 tons valued at $3,597,132. Unsold stocks in bins December 31, 1941, totaled 907 tons of zinc concentrates and 1,276 tons of lead concentrates compared with 2,764 tons and 186 tons, respectively, as of December 28, 1940. Flotation concentrates comprised 53.6 percent of the sphalerite from the Oklahoma-Kansas area and 14.7 percent of that from Southwestern Missouri.

During 1941 Federal defense agencies made surveys covering all phases of the zinc- and lead-mining industry of the Tri-State region in an effort to determine under what conditions output could be increased or at least maintained at its present level during the next few years. The data obtained indicated that owing to depletion of ore reserves and rising operating costs the rate of production attained during the spring of 1941 (around 40,000 tons of zinc concentrates

and 4,300 tons of lead concentrates monthly) was close to the maximum that the field could produce at the prices then prevailing for concentrates. Measures subsequently taken by the Government, which greatly improved the outlook for maintaining and expanding production, were a raise of 1 cent a pound in the price of zinc allowed on October 9, which brought an increase of $6.70 a ton in the price of zinc concentrates at Joplin; the granting of high-priority preference ratings on mine supplies and equipment, which became operative in the Tri-State district late in October; approval early in January 1942 of an advance of 0.65 cent a pound in the price of lead; and announcement of the plan to pay premium prices for over-quota production of copper, lead, and zinc for a 2½-year period beginning February 1, 1942.

The premium prices applied to concentrates of the Tri-State district amount to $28.05 a dry ton of 60-percent zinc concentrates and $39.60 for 80-percent lead concentrates. On March 1, 1942, Leslie H. McColgin was designated representative for the Metals Reserve Co. to handle premium payments on the production of Tri-State sulfide concentrates in excess of monthly quotas. The settlement plan is essentially as follows: Each producer who is eligible for the premium submits a request to McColgin, listing the total amount of concentrates delivered and sold for which payment has been or will be made and the amount of such concentrates which, being excess production, is eligible for a premium; he also furnishes a sworn affidavit. McColgin compiles statements of all requests received in a given period and sends them, with the sworn producers' affidavits, to the Metals Reserve Co., which arranges for premium payments to be made; checks made payable to the producers are sent to McColgin for distribution. Any deficiency in monthly deliveries of a given metal below the monthly production quota of any producer must be made up in the next succeeding month or months before such producer can receive any premium payment on excess-quota production of that metal. The first premium-payment checks made out to Tri-State operators were delivered March 17, 1942.

Production of recoverable zinc in Southwestern Missouri increased from 12,470 tons in 1940 to 20,832 tons in 1941 and lead decreased from 2,144 to 1,521 tons. About 80 mines and 26 mills, large and small, produced in 1941, compared with 80 and 17, respectively, in 1940. The Oronogo and Wentworth-Stark City areas contributed 67 percent of the total zinc output in 1941. At Oronogo, the Oronogo Mutual Mining Co. extracted 202,072 tons of ore from the Oronogo Circle open pit and in addition removed 409,790 tons of waste rock and overburden. The ore was milled in the Eagle-Picher American mill. From January to June, Kansas Explorations, Inc., sank two shafts, erected a hoisting derrick, and built a 600-ton mill on its Snapp property 2½ miles northwest of Oronogo; mining and milling were begun in July and continued the remainder of the year. The F. & M. Mining Co. operated the La Tosca mine and mill, and Fenix & Sons shipped crude ore from a shaft on the Oronogo Mutual property to the Central mill in Oklahoma. The output from the Wentworth-Stark City area came largely from the Dungy, Navy Bean, and Reynolds mines, operated by the Eagle-Picher Mining & Smelting Co., which milled the ore in its Navy Bean mill, completed in December 1940. The Wentworth Mining & Milling Co. and the Midwestern Mining & Sand Co. mills near Wentworth were operated part of 1941.

About October 20 the Federal Mining & Smelting Co. resumed operations at its Granby-American group of mines and mill, which had been shut down for 15 years. At Stotts City the Capital Mining Co. mine and mill were operated from June to December, except for time lost when the mine was flooded by heavy rains in October. The Stotts City Mining Co. worked on unwatering and developing its property. The Playter 100-ton custom mill near Waco milled ore from the Waco, Belleville, and Carthage area; and the F. W. Evans and St. Louis No. 9 mills in Kansas treated considerable ore mined from the Missouri part of the Waco district. In the Thoms station area the St. Louis Mining & Milling Co. operated its mill (old Grasselli) intermittently on ore mined by lessees on the Tabor-Velie land. The Sciota Milling Co. 1,000-ton tailing mill, built on the Missouri Zinc Fields Co. land near Webb City early in the year, was operated steadily after April. About 10 small mills in the vicinity of Webb City, Joplin, Alba, and Spurgeon were operated intermittently. Lessees on the Connor Investment Co. land in the Chitwood area shipped ore to custom mills. In November the Northside Mining Co. struck a rich deposit of zinc ore at a depth of 160 feet while sinking a shaft on the leased St. Louis-Joplin Lead & Zinc Co. land ½ mile northwest of Chitwood. The Mary Arnold mine and mill near Ozark (taken over in August by the Nibeck Mining Co.) continued producing. At Aurora the Harris Mining Co. completed a mill on the Scott-Phelps-Scott property and produced 85 tons of sphalerite. Zinc carbonate from scattered small mines and low-grade zinc-lead concentrates from the Goade mill at Granby shipped in 1941 totaled 1,277 tons.

OKLAHOMA

The method of marketing concentrates, prices quoted for them in 1941, and other general details of mining in the Tri-State region—which includes northeastern Oklahoma—are given in the preceding pages on Southwestern Missouri. Zinc and lead concentrates recovered from Oklahoma ores and old tailings had a combined value of $17,630,111, a 23-percent increase over 1940. The output of zinc concentrates increased 2 percent in quantity and lead concentrates 17 percent. About 120 mines produced during the year, and 27 mills were operating at the end of the year compared with 100 and 31, respectively, in 1940. Old tailings treated in Oklahoma in 1941 exceeded crude ore by 4,147,947 tons, and the tailings yielded 21 percent of the total zinc concentrates.

Mine shipments of lead and zinc in Oklahoma, 1937–41

Year	Lead concentrates (galena)		Zinc concentrates (sphalerite)		Metal content [1]			
					Lead		Zinc	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1937	39,446	$2,729,690	255,839	$10,428,354	29,840	$3,521,120	135,696	$17,640,480
1938	27,608	1,446,058	208,484	6,390,422	21,004	1,932,368	112,924	10,840,704
1939	36,422	2,189,077	258,214	8,937,554	27,720	2,605,680	140,379	14,599,416
1940	27,913	1,656,497	300,984	12,672,186	21,240	2,124,000	162,935	20,529,810
1941	32,628	2,202,876	307,207	15,427,235	25,021	2,852,394	166,602	24,990,300

[1] In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

Tenor of lead and zinc ore, old tailings, and slimes milled and concentrates produced in Oklahoma, 1940–41

	1940		1941	
	Crude Ore	Old tailings and slimes	Crude ore	Old tailings and slimes
Total ore, etc., milled.....short tons	4,195,400	7,055,000	4,868,021	9,015,968

Sphalerite concentrates	42.40	40.95	50.55	48.94

[1] Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates; data on tailing losses not available.

The Eagle-Picher Mining & Smelting Co. continued to be the largest producer of both lead and zinc in Oklahoma and in the Tri-State region. The company Central mill near Cardin has a capacity of 13,000 tons daily and treats company and custom ore. New installations made in the mill in 1941 included a secondary differential-density cone to be used as a supplement to the primary cone unit, which has been in operation since February 1939, and eight sludge tables for separating a special blende product for shipment to the zinc oxide plant adjoining the company lead smelter at Galena, Kans. The total ore treated in 1941 was 3,311,144 tons compared with 2,795,963 tons in 1940. Company-operated mines in Oklahoma shipping to the mill were the Blue Goose mines, Crystal mines, Eagle-Picher Gordon Nos. 1 and 2, Grace Walker mines, Hum-bah-wat-tah mines, Jay Bird, John Beaver mines, Little Greenback, Ohimo, See Sah, Southside mines, Stanley, Swift, and Wesah Greenback. The principal shippers of Oklahoma custom ore were the Baird Mining Co. (American-Douthat), Cameron & Henderson (Admiralty, Kitty), Cortez-Childress, Davis-Big Chief Mining Co. (Eudora-Whitebird), F. W. Evans (Shorthorn, etc.), Jane E. Mining Co. (McKibben, Scott), Lula Bell Mining Co. (Anna Beaver), M. & M. Mining Co. (Piokee, Swift), and Mahutska Mining Co. (Acme). The Eagle-Picher 2,400-ton Bird Dog mill was shut down in April and remained idle the rest of the year.

The Gordon central mill of the Federal Mining & Smelting Co. treated company ore from the Gordon, Lucky Bill, Lucky Syndicate, and Quapaw-Davenport mines in Oklahoma and the Federal Jarrett in Kansas. The Beck Mining Co. mill treated company and custom ore. Evans Wallower Zinc, Inc., ran its No. 4 and No. 7 mines and mills steadily. The M. & W. Mining Co. mined and sent to the Bilharz mill in Kansas a considerable tonnage of ore of higher than average grade from the L. D. Brewster mine. Operation of the Woodchuck and Townsite mines and the Woodchuck mill in Oklahoma and the Cherokee mine in Kansas was taken over on December 12, 1941, by the Weidman Mining Co.; the Oklahoma Interstate Mining Co.,

which had operated them for many years, became inactive. The Skelton Lead & Zinc Co. closed its mill in December and began shipping to the Central mill. Other producers of concentrates from mine mills in Oklahoma comprised Kansas Explorations, Inc. (Ritz); Rialto Mining Corporation (No. 3 mill); Lawyers Lead & Zinc Co. (mine "dirt" and tailings); Lavrion Mining Co.; Lula Bell Mining Co.; Mission Mining & Royalty Co. (custom "dirt"); St. Louis Smelting & Refining Co. (No. 4 mill); United Zinc Smelting Corporation (company and custom ore); Davis-Big Chief Mining Co. (Kropp mine); Hudson Lead & Zinc Co. (Goodeagle); Guaranty Mining & Royalty Co.; Roan Bull Mining Co.; and Smoky Hill Mining Co.

Companies operating tailing mills in Oklahoma comprised the Atlas Milling Co., Big Chief Tailing Co., Britt & Britt Milling Co., Cardin Mining & Milling Co. (Nos. 2 and 3), Rialto Mining Corporation, C. Y. Semple, Tri-State Zinc, Inc. (Sooner and Ottawa), and Western Mining & Milling Co.

No production was reported in the Peoria area or the Davis (Murray County) district in 1941.

WISCONSIN

During the 10-year period ended with 1940 the annual output of recoverable zinc from Wisconsin averaged 7,295 tons and that of lead 607 tons; this comprised all the output of the Upper Mississippi Valley region except 6 tons of zinc and 8 tons of lead produced in Northern Illinois in 1940, as mines in Iowa yielded no zinc or lead from 1918 to 1941, inclusive. In 1941 mines in Wisconsin yielded 6,238 tons of zinc and 1,225 tons of lead and those in Northern Illinois 1,718 and 120 tons, respectively—a total for the Upper Mississippi Valley region of 7,956 tons of zinc and 1,345 tons of lead compared with 5,776 and 453 tons, respectively, in 1940.

Shipments of crude ore and zinc-iron-lead rougher jig concentrates to the Vinegar Hill Zinc Co. central flotation mill at Cuba City rose sharply during the latter part of 1941, necessitating a 50-percent enlargement in the capacity of the mill. The mill made zinc concentrates (averaging 59.50 percent zinc), lead concentrates, and iron sulfide concentrates that were roasted to produce sulfuric acid. The principal shippers of custom mine "dirt" to the mill were the McCabe Mining Co. and Strawberry Blonde Mining Co. in the Benton district; the Depp Mining Co., Cuba City; the Meloy & Baker Mining Co., New Diggings; Arensdorf & Murray and the St. Joe Mining Co., Platteville; and Gill Brothers, Northern Illinois. Shippers of jig mill concentrates were the Big Jack Mining Co., Platteville; C. F. & H. Mining Co., New Diggings; Cuba Mining Co., Shullsburg; Four S. & B. Mining Co., Dodgeville; and Little Benny Mining Co., New Diggings. The Vinegar Hill Zinc Co. closed its Mullen No. 2 mine in April. The Dodgeville Mining Co. operated its 150-ton jig mill and 50-ton flotation mill (placed in operation December 20, 1940) throughout 1941; the zinc concentrates made in the flotation mill averaged 61.24 percent zinc. Several cars of zinc carbonate were shipped from the Clark No. 2 mine in the Highland district.

Mine production of lead and zinc in Wisconsin, 1937–41

Year	Lead concentrates		Zinc concentrates (sphalerite)		Metal content [1]			
					Lead		Zinc	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

[1] The zinc concentrates shipped in 1938 (3,895 tons) were a flotation product or raw concentrates roasted at Cuba City, Wis. No raw concentrates were shipped in 1938, about 13,000 tons, averaging 18 5 percent zinc, were produced.

[2] All sphalerite shipped in 1939 (10,169 tons) was a flotation product No raw concentrates were shipped in 1939; 32,360 tons, averaging 20 2 percent zinc, were produced.

[3] Percentage represents finished flotation concentrates Most of the ore mined in Wisconsin in 1940 and 1941 was first treated in gravity-concentration mills producing bulk concentrates which were re-treated by flotation. A considerable quantity of crude ore was floated direct

[4] Percentages represent metal content of the ore insofar as it is recovered in the concentrates.

[5] Value is that of roasted or flotation concentrates shipped. No value can be assigned for zinc concentrates prior to roasting or re-treatment by flotation.

[6] Value is that of flotation concentrates shipped

GOLD, SILVER, COPPER, LEAD, AND ZINC IN COLORADO

(MINE REPORT)

By Chas. W. Henderson and A. J. Martin

SUMMARY OUTLINE

SUMMARY

Colorado mines yielded gold, silver, copper, lead, and zinc valued, in terms of recovered metals, at $23,877,597 in 1941 compared with $24,293,665 in 1940. (See fig. 1.) Gold and silver together represented 77 percent of the total value in 1941 and 81 percent in 1940. Gold production increased 3 percent over 1940 and was the highest since 1924. The quantity of silver and copper produced decreased 25 and 44 percent, respectively, lead increased 10 percent, and zinc increased 211 percent. The output of zinc was 31,444,000 pounds, compared with 10,120,000 pounds in 1940 and with an annual average of 3,792,250 pounds in the 8-year period from 1932 to 1939. The number of large producing lode mines was about the same as in 1940; the number of placer operations (large and small) decreased, but the entire gain in gold production of the State came from the placers.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35 00	$0.7735	$0 121	$0 059	$0 065
1938	35.00	[4].646+	098	046	048
1939	35 00	[5] 678+	104	047	.052
1940	35.00	[6] 711+	113	050	063
1941	35 00	[6] 711+	118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934 Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938–41· Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers
[4] $0.64646464.
[5] $0.67878787.
[6] $0.71111111.

Annual figures for the 5 years ended with 1941 and total production from 1858 to 1941 are given in the table that follows. Colorado has produced more silver in the past than any other State and ranks second in total recorded output of gold.

Mine production of gold, silver, copper, lead, and zinc in Colorado, 1937–41, and total, 1858–1941, in terms of recovered metals

Year	Mines producing		Ore sold or treated (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1937	655	490	2,068,619	368,905	$12,911,675	6,260,693	$4,842,646

(1) Dragline and power-shovel excavators with sluices or special amalgamators.

Gold.—The output of gold from lode mines in Colorado in 1941 varied little from 1940, but that from placer mines increased 13,377 ounces (79 percent), owing mainly to production from new dredging operations in Park County. The Cripple Creek district, Teller County, continued to be the principal gold-producing district in the State; it was followed, in order, by the Red Cliff district, Eagle County; Upper San Miguel, San Miguel County; Mosquito, Park County; Leadville, Lake County; Animas, San Juan County; Summitville, Rio Grande County; Empire, Clear Creek County; Southern districts, Gilpin County; Idaho Springs, Clear Creek County; Gold Hill,

Boulder County; Sneffels, Ouray County; and Fairplay, Park County. Each of these districts yielded more than 10,000 ounces of gold. The largest gains over 1940, by counties, were 10,137 ounces in Lake County, 7,270 ounces in Park, 4,538 ounces in Teller, 4,344 ounces in Gilpin, and 4,342 ounces in Rio Grande; the largest decreases were 6,005 ounces in Eagle County, 5,084 ounces in Clear Creek, 3,246 ounces in San Miguel, and 2,892 ounces in Boulder. Dry and siliceous ores yielded 80 percent of the total gold; copper ore, 7 percent; zinc-lead, lead, zinc, and lead-copper ores, 5 percent; and placers, 8 percent.

Silver.—The mine production of silver in Colorado was 7,301,697 ounces in 1941—a decrease of 2,409,012 ounces from 1940. Eagle County continued to be by far the largest producer of silver in the State, although its output decreased from 6,766,726 ounces in 1940 to 4,352,677 ounces in 1941. Variations in output in other important silver-producing counties were decreases of 32,906 ounces in Clear Creek County, 13,247 ounces in Dolores, 90,744 ounces in Ouray, 27,852 ounces in Pitkin, and 18,499 ounces in San Miguel and increases of 39,340 ounces in Lake County, 40,310 ounces in Mineral, and 170,069 ounces in San Juan. Copper ore yielded 59 percent of the total silver; dry and siliceous ores 30 percent; and other types of ore, with a very small quantity of silver from placer mines, 11 percent.

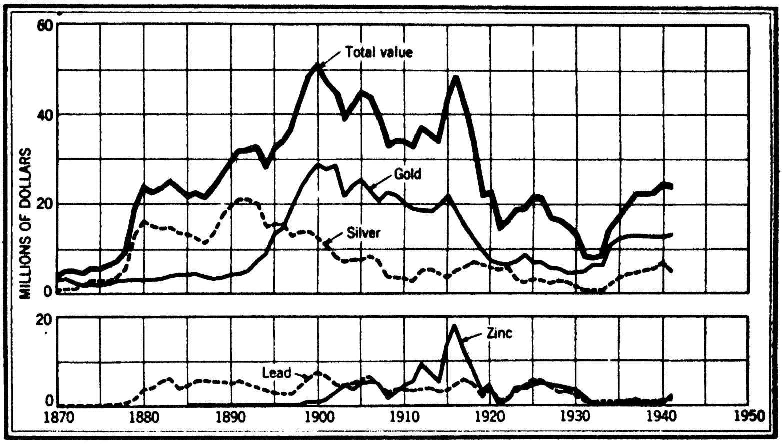

FIGURE 1.—Value of mine production of gold, silver, lead, and zinc and total value of gold, silver, copper, lead, and zinc in Colorado, 1870–1941. The value of copper has been less than $2,000,000 annually, except in a few years.

Copper.—The mine output of recoverable copper in Colorado was 13,496,000 pounds in 1941 compared with 24,304,000 pounds in 1940. The only sizable producer of copper in the State in either year was the Empire Zinc Division "Eagle Mine" of the New Jersey Zinc Co. at Gilman, Eagle County, which continued to ship copper-iron-silver-gold-lead ore direct to the copper smelter at Garfield, Utah. About June 15, 1941, the company began also to mine and mill zinc-lead ore in quantity, with greatly decreased output of copper-bearing ore. The copper output from other counties in the State came chiefly from zinc-lead ore and dry and siliceous ore; those that contributed more than 100,000 pounds of recoverable copper during the year were Boulder, Clear Creek, Dolores, Gilpin, Jefferson, Lake, Ouray, and San Juan.

Lead.—The mine production of lead in Colorado was 25,148,000 pounds in 1941 compared with 22,952,000 pounds in 1940. The output in 1941 came chiefly from San Juan, Dolores, Eagle, San Miguel, Lake, and Mineral Counties, each of which contributed more than 1,000,000 pounds. Zinc-lead ore yielded 53 percent of the total lead; dry and siliceous ore, 32 percent; and lead, copper, zinc, and lead-copper ores together, 15 percent.

Zinc.—Mines in Colorado yielded 31,444,000 pounds of recoverable zinc in 1941 compared with 10,120,000 pounds in 1940. The large increase in 1941 resulted from resumption of the mining and milling of zinc-lead ore by the New Jersey Zinc Co. Empire Zinc Division at its Eagle mine at Gilman, Eagle County. From 1932 to 1940, inclusive, the zinc-lead ore bodies in this mine were not worked, and the 600-ton underground flotation mill was idle. The total output of zinc from other mines in Colorado decreased slightly from 1940; and the principal producers in both years were the Rico Argentine Mining Co. at Rico, Dolores County, and the Shenandoah-Dives Mining Co. at Silverton, San Juan County.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Colorado in 1941, by counties, in terms of recovered metals

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)

[1] Dragline and power-shovel excavators with sluices or special amalgamators.

MINING INDUSTRY

In 1941 the output of dry and siliceous gold, gold-silver, and silver ores from mines and dumps in Colorado increased 3 percent and zinc-lead ore 53 percent over 1940, whereas copper ore decreased 38 percent and lead ore 22 percent. This sharp variation from 1940 in the State total output of zinc-lead and copper ores is explained by the fact that in 1940 the output of the Eagle mine in Eagle County, largest producer of copper and silver in the State since 1930, consisted entirely of copper ore (carrying iron, gold, silver, and lead), whereas in 1941, although the total tonnage was approximately the same as in 1940, part of the output was copper ore and part zinc-lead ore. The total quantity of zinc-lead ore mined in other counties in the State increased 9 percent. The increase in output of dry and siliceous ores in 1941 came from the Ibex dumps in Lake County. In July 1941 the Golden Cycle Corporation completed the driving of the 32,262-foot Carlton drainage tunnel in the Cripple Creek district, permitting renewal of mining on the lower levels of the Ajax and Cresson mines. The Resurrection Mining Co. at Leadville continued development work at its property and nearly completed construction

of a 250-ton zinc-lead flotation mill; the mill was placed in operation February 1, 1942. The South Platte Dredging Co. completed and put in operation its new floating connected-bucket dredge on the Platte River near Fairplay, and Cooley Bros. installed and operated a dragline floating dredge near Como.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Colorado in 1941, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	1, 234, 025	277, 160	401, 609	797, 207	2, 422, 510	
Dry and siliceous gold-silver ore	270, 267	27, 067	622, 763	141, 481	3, 581, 952	
Dry and siliceous silver ore	68, 471	967	1, 200, 260	42, 690	2, 003, 656	254, 000
	1, 572, 763	305, 194	2, 224, 632	981, 378	8, 008, 118	254, 000
Copper ore	207, 678	25, 187	4, 306, 343	11, 479, 396	1, 678, 029	
Lead ore	7, 917	1, 455	73, 496	30, 392	2, 165, 829	
Lead-copper ore	4	4	442	339	618	
Zinc ore	224	77	756	2, 400	6, 153	107, 071
Zinc-lead ore	434, 200	17, 735	690, [illegible]41	1, 002, 095	13, 289, 253	31, 082, 929
	650, 023	44, 458	5, 071, 378	12, 514, 622	17, 139, 882	31, 190, 000
Total, lode mines	2, 222, 786	349, 652	7, 296, 010	13, 496, 000	25, 148, 000	31, 444, 000
Total, placers		30, 377	5, 687			
	2, 222, 786	380, 029	7, 301, 697	13, 496, 000	25, 148, 000	31, 444, 000
Total, 1940	2, 157, 765	367, 336	9, 710, 709	24, 304, 000	22, 952, 000	10, 120, 000

METALLURGIC INDUSTRY

Ore treated in 1941 by all mills in Colorado handling ores of gold, silver, copper, lead, and zinc totaled 1,970,253 tons, of which 1,379,077 tons were treated in company mills at mines and dumps; 532,127 tons by the Golden Cycle custom roast-amalgamation-cyanidation-flotation mill at Colorado Springs; and 59,049 tons by the following custom concentration mills (some of which also treated company ore included above) in or near the mining districts: Orphan Boy in Boulder County; Black Eagle, Clear Creek-Gilpin, Red Elephant, Ruth, and Watrous (Silver Leaf) in Clear Creek County; Eldorado in Hinsdale County; Creede Mills (Emperius) in Mineral County; Banner American in Ouray County; Record in Park County; Shenandoah-Dives in San Juan County; Smuggler-Union in San Miguel County; and Cameron in Teller County. All these custom mills except the Shenandoah-Dives and Banner American treated gold, gold-silver, or silver ores, with a minor content of lead and copper. Zinc-lead ore (4,913 tons) containing gold and silver and some copper, from Boulder, Chaffee, Dolores, Gunnison, Lake, Ouray, Saguache, San Juan, and Summit Counties, was shipped to custom mills at Bauer, Midvale, and Tooele, Utah. The ore-sampling works at Boulder was run part of 1941; the sampler at Idaho Springs was idle throughout the year.

Direct-smelting ores comprised 11 percent of the State total output of ore in 1941. The Arkansas Valley lead bullion-leady copper matte smelter at Leadville purchased most of the gold, silver, and gold-silver-lead-copper ores and concentrates shipped to smelters during the year. Ore and concentrates were shipped to smelters in other States as

follows: Zinc-lead sulfide ores and concentrates from Lake, Saguache, and Summit Counties to Coffeyville, Kans.; zinc concentrates from Clear Creek, Dolores, Ouray, Park, Pitkin, San Juan, and Summit Counties to Amarillo, Tex.; and copper-iron-silver-gold ore from Eagle County, copper-silver and copper-silver-gold ores and concentrates from Custer, Garfield, Jefferson, Larimer, and Montrose Counties, and gold-silver-lead-copper ores and concentrates from the San Juan region to Utah smelters.

The quantity of gravel handled in 1941 by 2 floating connected-bucket dredges, 1 dragline floating dredge, and 31 dry-land dredges was approximately 5,322,300 cubic yards averaging 18.74 cents to the yard. Specific data on yardage handled at small-scale placer operations are not obtainable because of lack of knowledge by the operators of the quantity of gravel sluiced.

Mine production of metals in Colorado in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore and concentrates amalgamated [1]	1,040,093	78,933	18,513			
Ore, old tailings, concentrates, sands, and slimes cyanided [2]	[3] 578,261	124,258	35,101			
Concentrates smelted	106,124	111,198	2,404,131	2,110,994	20,199,890	31,404,929
Ore smelted	247,620	35,263	4,838,265	11,385,006	4,948,110	39,071
Placer [1]		30,377	5,687			
		380,029	7,301,697	13,496,000	25,148,000	31,444,000
Total, 1940		367,336	9,710,709	24,304,000	22,952,000	10,120,000

[1] Quicksilver used by amalgamation mills was 3,489 pounds. Placer mines used approximately 550 pounds

[2] Cyanide (in terms of 96- to 98-percent NaCN) used was 641,045 pounds.

[3] Comprises 355,349 tons of sands and slimes from ore and iron concentrates first roasted and amalgamated, 176,778 tons of tailings from ore first floated, 26,483 tons of tailings from ore first treated by jigging, and 19,651 tons of combined flotation concentrates, crude ore, and old tailings cyanided direct.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Colorado in 1941, by counties, in terms of recovered metals

ADAMS COUNTY

Nearly all the output of gold and silver from Adams County in 1941 was recovered as a byproduct from the gravel-washing plants of the Brannan Sand & Gravel Co. and the United Sand & Gravel Co. near Denver.

ARAPAHOE COUNTY

A lessee on the Tresize placer, which extends across the county line into Jefferson County, produced 22 ounces of gold and 4 ounces of silver from the Arapahoe County area in 1941.

ARCHULETA COUNTY

Seven tons of gold-silver ore were shipped to the Leadville smelter from the Last Dollar claim.

BOULDER COUNTY

Central (Jamestown) district.—The Wano mine continued in 1941 to be the principal producer of gold in the Central district; it was operated throughout the year by the owner and several sets of lessees, who shipped the ore to the Golden Cycle mill at Colorado Springs. A lessee at the Smuggler group shipped ore from the mine and dump to the Golden Cycle mill. Associated Metal Mines, Inc., worked the John Jay mine from January 1 to March 31 and shipped 163 tons of ore. Among the other producers of gold were the Black Rose group, Golden Age, and Gray Eagle. About 50 tons of zinc-lead ore were shipped from the Central district to the Midvale (Utah) custom concentrator.

Gold Hill district.—Slide Mines, Inc., operated its Slide-Klondyke-Twin group of mines and 70-ton gravity- and flotation-concentration mill throughout 1941. The gold concentrates caught on burlap tables between the classifier and Wilfley tables were amalgamated, and the rest were shipped to the Leadville smelter. Besides gold and silver, the concentrates shipped to the smelter contained some recoverable copper and lead. The ore from the other producing mines and dumps in the Gold Hill district was shipped to the Golden Cycle mill or the Boulder Ore Sampler. Sizable producers, in order of gold output, were the Ingram group, Sunshine, Emancipation, Melvina, Nil Desperandum, and Little Johnny.

Grand Island district.—The Donora Mining Co. operated the Boulder County mine and 70-ton jig- and flotation-concentration mill under lease throughout 1941, producing gold-silver-lead concentrates which were shipped to the Leadville smelter. Ore was shipped to the Golden Cycle mill and Leadville smelter from the Amy Paul, Blue Bird, Enterprise, Revenge, and other small mines in the Grand Island district.

Magnolia district.—The producing mines in the Magnolia district in 1941 were the Cash-Rebecca, Fortune, Graphic, Hereafter, India, LeRoy, Ben C. Lowell, and Senator Hill.

Sugar Loaf district.—Most of the ore produced from mines and dumps in the Sugar Loaf district in 1941 was shipped to the Golden Cycle mill. The Poorman group continued to be the principal producer of gold; it was followed by the Alpine Horn, Nancy, Wood

Mountain, Grand Republic, and Keystone, each of which yielded more than 100 ounces of gold. The silver output came chiefly from silver ore from the Yellow Pine group and gold ore from the Nancy.

Ward district.—The Ward United Mines Co. operated the Boston-Utica group throughout 1941 and reconditioned the Utica 25-ton concentration mill, which was placed in operation in July. The concentrates and crude smelting ore shipped contained in all 2,535 ounces of gold, 2,872 ounces of silver, and 49,661 pounds of copper. Small tonnages of ore were shipped to the Leadville smelter or the Golden Cycle mill from the B & M mine, Baxter, Captain Jack, Columbia, Golden Queen, Grandview, Hard Rock, Hawkeye, Helen B, and Nelson.

CHAFFEE COUNTY

Chalk Creek district.—Lessees operating the old Mary Murphy mine on a small scale shipped ore containing gold, silver, lead, copper, and a relatively high percentage of zinc to the Midvale (Utah) custom milling plant and selected ore of a similar type but lower in zinc content to the Leadville (Colo.) smelter. A small quantity of lead ore was shipped from another property in the Chalk Creek district.

Four Mile district.—Harry Ault shipped 67 tons of zinc ore containing gold, silver, lead, and copper to the Midvale (Utah) custom concentrator in 1941.

Granite district (see also Lake County).—Only 10 tons of ore yielding 8 ounces of gold and 10 ounces of silver were shipped from lode mines in the Granite district in 1941. Len Savage operated his placer in Lost Canyon intermittently from June to September, using a power shovel and screening-sluicing plant. Wolfe & Hesser operated a ¾-cubic yard power shovel and screening and sluicing plant in Lost Canyon and on Cache Creek from July 12 to August 19. The Cache Creek, Franklin, Independent, Mizer, and other placers on Arkansas River near Granite were worked on a small scale with sluices, and drift mining was done at the Old Channel and Georgia Bar placers.

La Plata district.—A 2-ton lot of gold-silver-lead ore from the Tip Top claim was shipped to the Leadville smelter in 1941.

Monarch district.—A lessee at the Madonna group shipped 12 tons of gold-silver-lead ore in 1941, and another operator in the Monarch district shipped 16 tons of gold-silver-lead-copper ore.

Red Mountain district.—A small lot of gold-silver ore was shipped from the Anchor group to the Golden Cycle mill in 1941.

Turret district.—Small lots of ore were shipped from the Golden Wonder and Monongahela mines to the Golden Cycle mill.

CLEAR CREEK COUNTY

Alice district (Yankee, Lincoln).—A lessee at the Lombard mine shipped 829 tons of gold ore containing some silver, lead, and copper to custom mills in the Idaho Springs district in 1941. The Gold King mine yielded 203 tons of gold-silver ore, part of which was shipped to the Golden Cycle mill at Colorado Springs and part to the Clear Creek-Gilpin mill at Idaho Springs. Other small producers in the Alice district were the Lalla, San Juan, Reynolds, and Whale mines.

Argentine district.—Buckley Bros. operated the Hamill tunnel group in 1941 and produced 601 tons of silver ore, of which 527 tons were concentrated in local custom mills and 74 tons were shipped crude to

the Leadville smelter. The 50-ton flotation mill at the Santiago mine was operated during the summer months; the concentrates produced, containing gold, silver, lead, and copper, were shipped to the Leadville smelter. Some ore from the Paymaster group was shipped to the Ruth custom mill at Idaho Springs.

Empire district.—In 1941 Minnesota Mines, Inc., operated continuously its consolidated group of claims in the area north of Empire; since 1935 this company has been the largest producer of gold in Clear Creek County. The output was 15 percent less in 1941 than in 1940. The ore is treated in the 250-ton mill at the mine by concentration on mats in launders and by flotation followed by cyanidation of the flotation concentrates. After cyanidation the flotation concentrates, containing chiefly iron sulfide, are sold to the General Chemical Co. of Denver for the manufacture of sulfuric acid; the mat concentrates, containing mostly free gold, are amalgamated. Copper Cone, Inc. made a substantial output of gold from the Upper Union-Gold Fissure group; the ore was treated in the Clear Creek-Gilpin and Ruth custom mills at Idaho Springs. The Conqueror Operating Co. shipped 425 tons of gold-silver ore from the Conqueror group to the Clear Creek-Gilpin mill. Other small producers included the Ashland, Cashier, Gold Dirt, Mint, and Pittsburg properties.

Griffith (Georgetown-Silver Plume) district.—The Mile High Mining Co. began work at the Smuggler group in January 1941 and in August began to mine and mill ore. Production to the end of the year was 145 tons of zinc concentrates, shipped to the Amarillo (Tex.) smelter, and 45 tons of lead-silver concentrates, shipped to the Leadville smelter. Ore was shipped to custom mills at Idaho Springs from the Clara B, Hall tunnel, and St. George groups and to the Leadville smelter from the Fargo and Johnny Bull properties.

Idaho Springs district.—The Alma-Lincoln Mining Co., a consistent producer since 1933, operated its Lincoln-South Lincoln-Elliott Barber group and flotation mill throughout 1941 and treated 25,019 tons of ore, compared with 36,404 tons in 1940. The company, which had purchased the Metropolitan property in 1940, took a lease on the Dona Juanita and Cardigan claims in 1941. The Silver Spruce Gold Mining Co. operated its 50-ton mill at Idaho Springs on company ore from the Lord Byron mine from January to the first week in July and on custom ore the rest of the year. A large part of the custom ore came from the Shafter dump. Gold Mines Consolidated, owner and operator of the Dona Juanita-Maude Monroe group of mines and the Gustafson mill, produced and treated 5,613 tons (wet weight) of ore during the year. The Black Eagle mill was operated as a custom plant by S. S. Huntington; most of the ore treated came from the Williams, Diamond Joe, Specie Payment, Freighter's Friend, and Brighton mines. The ore from the last four mines contained, besides gold, considerable silver and lead and some recoverable copper. Other sizable producers of gold-silver-lead-copper ores shipped to custom mills were the Brighton, Hyland, and Idaho Bride. LeRoy Giles & Co. and the Ute Creek Syndicate continued to ship gold-silver ore from the Dixie No. 4 and East Dixie mines, respectively, to the Ruth custom mill. Other producers of more than 100 tons of ore included the Equinox, Golden Edge, Mattie group, Red Jacket, and East Santa Fe. The Banner Mining Co., working the Idaho placer ground, produced

most of the output of placer gold from the Idaho Springs district during the year.

Montana district (Lawson, Dumont).—The output of ore from the Montana district in 1941 comprised 150 tons of lead-silver-gold ore from the Red Elephant group and 25 tons from the Joe Reynolds.

Trail Creek district.—Lamartine Mines, Inc., operated the Lamartine-Falcon group of mines throughout 1941. The ore (29,508 tons) was treated in the company mill by flotation supplemented by jigs in the ball mill-classifier circuit to extract free gold for amalgamation. Bullion sold to the Denver Mint contained 1,788 fine ounces of gold and 461 fine ounces of silver, and concentrates shipped to the Leadville smelter contained 2,668 ounces of gold, 4,738 ounces of silver, 214,817 pounds of lead, and some zinc. Lessees at the Donaldson (Wheatland)-Little Champion group continued to ship ore to custom mills at Idaho Springs and the Golden Cycle mill at Colorado Springs. Other small producers included the Diamond Mountain-Lucky group, Harrisburg, and Lone Tree.

CONEJOS COUNTY

Lessees at the Forest King mine in the Platoro district shipped 45 tons of gold-silver ore to the Golden Cycle mill in 1941.

COSTILLA COUNTY

A car of zinc-lead ore was shipped from Jaroso to the Ozark pigment plant at Coffeyville, Kans., in 1941. Sluicing in Grayback Gulch on the property of the Drum Estate near La Veta recovered a few ounces of placer gold.

CUSTER COUNTY

Output from Custer County in 1941—mostly from the Hardscrabble district—comprised 168 tons of lead-silver ore from the Defender mine, 7 tons of copper ore from the Reito Alta, and 3 tons of lead ore from the High Kicker-Wild Girl group.

DENVER COUNTY

Sluicing on Platte River recovered 6 ounces of placer gold in 1941.

DOLORES COUNTY

Lone Cone district (Dunton).—Modern Gold Mines, Inc., continued to operate the Emma and Smuggler-Almont mines and the Emma 100-ton flotation mill under lease from January 1 to September 1, 1941. The concentrates produced contained gold, silver, and a little lead and were shipped to the Leadville smelter.

Pioneer district (Rico).—The Rico Argentine Mining Co. operated its group of mines and 135-ton selective-flotation mill continuously in 1941 at an average daily rate of approximately 100 tons of ore. The products of the mill were lead-silver concentrates (carrying some copper, zinc, and a little gold) shipped to the Leadville smelter and zinc concentrates (carrying also silver, lead, copper, and a little gold) shipped to the Amarillo (Tex.) smelter. Other output from Rico included zinc-lead-silver and lead-silver ores containing a little copper and gold shipped from the Pro Patria group, the St. Louis Smelting & Refining Co. property, and the Yellow Jacket group to custom mills and smelters in Utah.

DOUGLAS COUNTY

Individuals sluicing on Dry Creek and Newlin Gulch near Parker and Franktown in 1941 recovered small lots of placer gold.

EAGLE COUNTY

Mount Egley district.—A little gold was recovered in 1941 from the Katherine lode claim and a small placer mine on Lake Creek.

Red Cliff district (Battle Mountain).—In 1941 the Red Cliff district ranked first among Colorado districts in output of silver, copper, and zinc and was also an important producer of gold and lead. The Eagle mine, owned and operated by the New Jersey Zinc Co., Empire Zinc Division, was again the chief producer. The company shipped a large tonnage of copper-iron-silver-gold sulfide ore (but much less than in 1940) to the Garfield (Utah) smelter and from June to December operated its 600-ton underground flotation mill on zinc-lead ore, large reserves of which are also developed in the mine. The Ben Butler Corporation shipped 552 tons of gold-silver copper ore from the Ben Butler group to the Garfield (Utah) smelter. Other small producers were the Star of the West and Tip Top mines.

EL PASO COUNTY

GOLDEN CYCLE MILL

The Golden Cycle custom mill at Colorado Springs recovered 42 percent of the total Colorado output of gold from lode mines in 1941. It treated 532,127 tons of ore averaging 0.3038 ounce of gold to the ton compared with 550,521 tons averaging 0.2905 ounce in 1940. Of the total ore treated in 1941, 484,702 tons were gold-[silver]-sulfotelluride ores from the Cripple Creek district (Teller County) and 47,425 tons comprised miscellaneous gold and gold-silver ores from other districts, mainly in Boulder, Clear Creek, and Gilpin Counties. Approximately one-third of the total crude ore is treated by flotation- and table-concentration, and the concentrates obtained are mixed with the other two-thirds of crude ore and roasted. The calcines from the roasters are cooled and ground in Chilean mills to approximately minus-16-mesh and passed over blankets; the blanket concentrates are amalgamated in Wheeler pans and iron arrastres, and the blanket tailings are treated by cyanidation after sand-slimes separation. The concentration-plant tailings (flotation being in cyanide solution) also go to the cyanide plant. The amalgam and precipitates recovered are melted and cast into bars for shipment to the Denver Mint. On October 20, 1941, the mill placed in effect a new treatment schedule which increased the payment for gold $0.86 an ounce.

The cyanide plant of the Mill Tailings Recovery Co. at the old Portland mill dump near Colorado Springs was not operated in 1941.

FREMONT COUNTY

Lessees worked the Green Mountain mine near Hillside intermittently in 1941 and shipped 31 tons of copper-silver ore to the Leadville smelter. Jetter & Andrews shipped 2 tons of dump lead ore from Florence.

GARFIELD COUNTY

Rifle Creek district.—The Gray Eagle Mining Co. operated the Gray Eagle mine 8½ miles from New Castle intermittently in 1941, mostly on development, and shipped some gold-silver-copper ore to the Garfield (Utah) smelter. L. Harmon shipped a car of zinc ore containing a little gold, silver, copper, and lead from the Sunshine mine near Rifle to the custom mill of the International Smelting & Refining Co. at Tooele, Utah. A little ore was shipped from the O. G. and Paupers Dream claims near New Castle.

GILPIN COUNTY

Southern districts (Blackhawk, Central City, Nevadaville, Russell Gulch).—The Pittsburg-Notaway group of mines and 50-ton flotation mill were operated continuously in 1941 and yielded more than half of the total output of gold from lode mines in the Southern districts of Gilpin County during the year. Operations from January to July were carried on under lease by J. C. B. Millard and during the rest of the year by Kingmill Mines, Inc. The concentrates contained, besides gold, considerable copper and silver and were sold to the Leadville smelter. The California-Hidden Treasure Mines Co. worked the Monmouth-Kansas mine throughout the year, sending the ore produced (1,580 tons) to the Clear Creek-Gilpin mill at Idaho Springs (Clear Creek County) for treatment. The recovery in bullion shipped to the Denver Mint and the content of concentrates sold to the Leadville smelter totaled 775 ounces of gold, 3,909 ounces of silver, 20,927 pounds of copper, and 9,307 pounds of lead. The company also shipped 504 tons of ore from its First National-Kansas group, operated through the Argo tunnel. Work on this group ceased about November 1, 1941. The New Brunswick mine and 15-ton stamp amalgamation-table concentration mill were operated throughout the year. Ore was shipped to the Golden Cycle mill at Colorado Springs and to custom mills in Clear Creek County from the Americus, Federal, Justice, Old Town group, Saratoga, West Notaway, and other mines and dumps in the Southern districts. Chain O'Mines Operators shipped a few cars of gold-silver-lead concentrates to the Leadville smelter.

Manion Placer Mines operated its land dredge on North Clear Creek from April 15 to November 19, 1941. The ground worked comprised the Van Fleet patented land and the Snowstorm, Deal, Independent, and Badger placers. The equipment included a 1½-cubic yard power shovel, ½-cubic yard dragline, caterpillar bulldozer, screening plant on crawlers, and separate sluicing plant on wheels. Other producing placers worked on a small scale with power shovels or draglines and screening and sluicing plants included the McElwee & James, Mission Mines Co., Nevada Gulch, Nugget, and Pleasant Valley. Individuals continued sluicing and panning during the open season on North Clear Creek.

Northern districts. The Perigo group was worked on a small scale by lessees during part of 1941. Most of the ore produced was concentrated in the mill at the mine, yielding gold-silver concentrates that were shipped to the Leadville smelter. One car of crude ore was sold to the Golden Cycle mill. Other shippers of small lots to the Golden Cycle mill were the Independent and Lone Star mines. A

little ore was shipped to the Leadville smelter and to custom mills in Clear Creek County from the Caledonia, McAdams, Providence-Newport, and two other lode properties in the Northern districts. The Gamble Gulch Mining Co. operated its ½-cubic yard dragline and sluicing plant during part of the year in Gamble Gulch. Individuals recovered a little placer gold by sluicing in Lump Gulch.

GRAND COUNTY

Small lots of silver-lead ore were shipped to the Leadville smelter in 1941 from the Bobtail claim in the La Plata district, the Ready Cash near Jones Pass, and the Wolverine about 22 miles north of Granby.

GUNNISON COUNTY

Domingo (White Earth) district.—A 1-ton lot of copper-gold-silver ore was shipped from the Good Smaritan claim in 1941.

Gold Brick district.—The Carter Mines Co. operated its mine and mill on Gold Creek throughout 1941. The ore was treated by amalgamation and by flotation- and gravity-concentration. Ore treated during the year totaled 8,451 tons, from which were recovered bullion containing 1,367 fine ounces of gold and 786 fine ounces of silver and concentrates containing 273 ounces of gold, 5,887 ounces of silver, and 9,008 pounds of lead. Burleson Mines, Inc., operated the Raymond group and mill about 6 months in 1941 and produced 670 tons of ore yielding 79 tons of concentrates containing 137 ounces of gold, 831 ounces of silver, and 20,233 pounds of lead. At the Bertha, Chicago, and Wayne mines small tonnages of ore were produced and treated in amalgamation-concentration mills. A little gold was recovered from the Goldsmith and Phyllis claims.

Green Mountain district.—Small lots of ore were shipped to the Leadville smelter in 1941 from the Chief and Prosperity claims.

Quartz Creek district.—Warner H. Thomas shipped 4 tons of ore containing lead, copper, silver, gold, and zinc to the Midvale (Utah) custom concentrator in 1941. A few tons of silver-lead and gold-silver-lead ore were shipped to the Leadville smelter from the Fairview mine and another property in the Quartz Creek district.

Rock Creek district.—The owners of the Carbonate claim shipped 2 tons of zinc ore containing a little gold, silver, and copper to the Midvale (Utah) custom concentrator in 1941. A 4-ton lot of silver-gold-lead ore was shipped to the Leadville smelter from the Black Eagle claim.

Taylor Park (Tin Cup) district.—In 1941 the Star and Thunderbird mines shipped 96 and 105 tons, respectively, of ore containing zinc, lead, copper, silver, and gold to the Midvale (Utah) custom mill, and the Trail Horse claim shipped 18 tons of gold-silver-lead ore to the Leadville smelter.

Tomichi district.—A sublessee at the Akron mine, under lease to the Callahan Zinc-Lead Co., Inc., shipped 2 cars of zinc-lead silver-gold ore to the Midvale (Utah) custom mill in 1941.

HINSDALE COUNTY

Galena district.—Davis Gold Mines operated the Eldorado 50-ton mill during part of 1941 on company and custom ores and shipped some copper-lead-silver-gold concentrates to the Leadville smelter. The ore milled included 16 tons from the Cherokee dump.

Lake district.—About 2 cars of silver-lead-copper-gold ore were shipped by lessees from the Belle of the West mine, and 1 ton of gold-silver-lead ore was shipped from the Pitkin claim in 1941.

JEFFERSON COUNTY

The old Malachite mine 3½ miles northwest of Morrison, which was reopened in 1940, was operated by lessees for a period during the first part of 1941. The ore produced was concentrated in the Furstenberg mill near Idaho Springs, and the concentrates produced were shipped to the Garfield (Utah) smelter. Later the mine was leased to the American Smelting & Refining Co. Most of the output of placer gold from Jefferson County during the year was recovered by W. B. Kerkling from the Bertrand gravel pit and the Tresize placer

LAKE COUNTY

LEADVILLE DISTRICT

The American Smelting & Refining Co. operated its Arkansas Valley lead bullion-leady copper matte smelter continuously (one furnace) in 1941 on ores and concentrates purchased from operators in virtually all the active mining districts of Colorado. Receipts totaled 121,297 tons compared with 114,371 tons in 1940.

A large part of the mine output of gold, silver, copper, and lead from the Leadville district in 1941 was derived from Ibex dump ore treated in the mills of the California Gulch Mining Co. and the H. G. N. Mining & Milling Co. (name changed to Hamm Mining & Milling, Ltd., September 1, 1941). The first company operated two mills, both equipped for gravity- and flotation-concentration and amalgamation. Mill No. 1, with a daily capacity of 125 tons, was built in 1939 and operated in 1940 and 1941. Mill No. 2 (daily capacity, 450 tons) was completed in May 1941 and operated from June 1 to the end of the year. The Hamm mill (formerly H. G. N.), built in 1937, was operated throughout 1941; it has a daily capacity of 300 tons. The process used is jig-, table-, and flotation-concentration and amalgamation of the cleaner jig concentrate. Ore treated in the three mills totaled 217,693 tons. Andy Caine & Co. treated 2,868 tons of ore from the Fanny Rawlings mine by table concentration and amalgamation in the leased Norton mill. The principal shippers of crude ore to the Leadville smelter (in approximate order of tonnage) were the "Lillian" group, Breece, Iron Hill, Ibex, Dolly B, New Monarch, Ollie Reed, and Little Ellen. Nearly 500 tons of zinc-lead-gold-silver ore from the New Monarch, Rock Hill, St. Louis tunnel, and Yak properties were shipped to the Midvale (Utah) custom concentrator, and 25 tons of zinc-lead ore from the Rock Hill property were sent to the Ozark pigment plant at Coffeyville, Kans.

The Resurrection Mining Co., continuing development work at the Resurrection mine, drove 6,718 feet of drifts and 336 feet of raises, reconditioned 4 miles of the Yak drainage-transportation tunnel and the surface plant at the tunnel portal, and nearly completed the building of a 250-ton flotation mill. The mine workings include a vertical shaft 1,290 feet deep and six levels. The Yak tunnel intersects the shaft at the 850-foot level. The mill was placed in operation

February 1, 1942; the products are lead concentrates (carrying gold, silver, copper, and some zinc) and zinc concentrates (carrying some gold, silver, copper, and lead).

OTHER DISTRICTS

No large producing lode mines operated outside the Leadville district in Lake County in 1941. Those making some output were the Mount Champion in the Lackawanna Gulch district; the Amity, Dinero, and St. Kevin in the St. Kevin-Sugar Loaf district; the Homestake in the Tennessee Pass district; and the Columbine and Gordon-Bengal Tiger in the Twin Lakes district. The Mt. Elbert Mining Corporation operated its dry-land dredge on the Derry Ranch placers in the Box Creek district 12 miles south of Leadville from April 27 to November 25. Small lots of placer gold were recovered at the Cureton and other placers near Granite and Twin Lakes.

LA PLATA COUNTY

California (or La Plata) district (Hesperus, La Plata).—Small tonnages of ore were shipped to the Leadville smelter in 1941 from the Bessie G, Hazel, Gold King, Gold Hope, May Day, and Mountain Lilly mines. A little placer gold was recovered by sluicing on the Eclipse property.

LARIMER COUNTY

Manhattan district.—Small lots of ore were shipped to smelters in 1941 from the Depression claim.

Masonville district.—Lessees at the Little Mary Mason mine shipped tons of gold-silver ore in 1941.

MINERAL COUNTY

Creede district.—Silver production in the Creede district increased 5 percent in 1941 over 1940, following a 45-percent increase in 1940 over 1939. The output of gold recovered from the silver ore also increased slightly in 1941, but that of lead decreased. Most of the ore was treated in the leased 100-ton flotation mill operated by the Emperius Mining Co.; the concentrates produced were shipped to the Leadville smelter. Shippers to the mill comprised the Amethyst group, Commodore, Equinox, and Emco-Chance. Part of the ore from the Commodore and Emco-Chance mines and that from the Ochre mine and the Weaver-Oates lease were shipped direct to the Leadville smelter.

MONTEZUMA COUNTY

The Red Arrow Gold Corporation operated its Red Arrow mine and 25-ton amalgamation mill approximately 9 months in 1941. The mill treated 2,500 tons of ore, and an additional 24 tons were shipped crude to the Leadville smelter. The total content in bullion and crude ore was 1,053 ounces of gold and 1,152 ounces of silver. The Outwest Mining Co. shipped 34 tons of gold-silver ore from the Outwest property, adjoining the Red Arrow.

MONTROSE COUNTY

La Sal district.—Lessees at the Cashin group shipped 270 tons of copper-silver-gold ore to smelters in 1941.

Naturita district.—Individuals sluicing on San Miguel River in 1941 recovered small lots of placer gold.

OURAY COUNTY

Red Mountain district.—The only shipments of ore from mines in the Red Mountain district in 1941 were 27 tons of lead-silver ore from the Mickey lease, 9 tons of zinc-lead ore from the Red Creek group, and 1 ton of lead-silver ore from a prospect.

Sneffels district.—King Lease, Inc., ran its 100- to 125-ton mill throughout 1941 on ore from the Camp Bird mine. The ore was transported from the mine workings to the mill through the 11,000-foot low adit. In treatment the ore was fed from the mill bins to jaw crushers and then to ball mills; the pulp from the ball mills was amalgamated on plates, and the pulp from the plates was sent to the flotation circuit where bulk gold-silver-copper-lead-[zinc] concentrates were made for shipment to smelters. The gold-silver bullion recovered was sold to the Denver Mint. The only other output of ore from the Sneffels district during the year was 10 tons of lead-silver ore from the Mountain Top claim and less than 1 ton of gold ore from another property.

Uncompahgre district.—G. A. Franz, Inc., operated its 120-ton flotation mill 2 miles north of Ouray in 1941 on custom ores from the Syracuse-Bachelor and Pony Express groups. The mill treated 4,862 tons of ore yielding 167 tons of lead-silver concentrates (containing some copper and gold) and 55 tons of zinc concentrates (containing also silver, lead, and a little gold and copper). The lead-silver concentrates were shipped to the Leadville smelter and the zinc concentrates to the Amarillo (Tex.) smelter. The McCullough Lease shipped gold-silver-copper ore from the American Nettie and Wanakah groups direct to smelters and treated 780 tons of old tailings from the Wanakah mill dump in the 50-ton flotation mill on the property. Small tonnages of smelting ore were shipped from other mines in the Uncompahgre district, including the Chief Ouray group, Newsboy, Portland, and Senorita.

PARK COUNTY

Alma Placers district.—The only substantial producer on the Alma Placers in 1941 was Jack Richards, who shipped gold to the Denver Mint steadily from May to October. The gravel was dug from open pits by power shovels and hauled by trucks to the central sluicing plant for treatment.

Beaver Creek district.—The Timberline Dredging Co. operated its electric floating connected-bucket dredge on Beaver Creek near Fairplay from April 27 to November 2, 1941, and handled 632,400 cubic yards of gravel; the dredge is equipped with 84 buckets, each with a capacity of 7½ cubic feet. Other producers from placers on Beaver Creek were the Detwiler Lease and E. E. Lytle.

Buckskin district.—The Phillips group was operated by 2–3–4 Mines, Inc., from January 1 to March 31, 1941, and by Buckskin

Joe Mines, Ltd., from April to the end of the year. The ore produced (4,539 tons) was treated by selective flotation in the leased Alma Betts 50-ton mill 6 miles from the mine. The products of the mill were zinc concentrates (carrying some gold, silver, copper, and lead) shipped to the Amarillo (Tex.) smelter and iron concentrates (containing gold, silver, lead, and zinc) and lead concentrates (carrying gold, silver, copper, and zinc) shipped to the Leadville smelter. A lessee at the Gold Ridge mine shipped 67 tons of zinc ore (containing gold, silver, copper, and lead) to the Midvale (Utah) custom mill and 41 tons of gold-silver-lead-copper ore to the Leadville smelter. Other small lode producers included the Buckskin and Kentucky Belle mines. Sluicing in Buckskin Gulch recovered a little placer gold.

Consolidated Montgomery district.—The Magnolia Gold Mining Co. continued in 1941 to work the Magnolia mine and produced 3,600 tons of gold-silver ore containing a little copper. The ore was transported by a 4,000-foot aerial tramway to the company mill in Montgomery Gulch and treated by table- and flotation-concentration. Small tonnages of ore were shipped to the Golden Cycle mill and the Leadville smelter from the Alice Lee, Creighton, Kansas, Ketsby, Lee Goss, and Prince Albert mines. About 5 ounces of placer gold were recovered in Montgomery Gulch.

Fairplay district.—The new 10,000-cubic yard (per day) steel connected-bucket dredge of the South Platte Dredging Co. began operating June 11, 1941, on bench ground along the Platte River near Fairplay and ran continuously the rest of the year. The dredge is powered by electricity and is equipped with 108 buckets, each with a capacity of 12 cubic feet. The Snowstorm placer north of Fairplay yielded a substantial output during the year. About 38 companies and individuals, several of whom used power shovels and land washing plants, worked on the property. Among the larger producers were the B. & H. Exploration Co., Philton Mines, and Miles O. Deatherage. Sluicing was done at other placers on Platte River near Fairplay.

Hall Valley district.—A lessee at the La Clede claim shipped 27 tons of gold-silver-copper-lead ore to the Ruth custom mill at Idaho Springs (Clear Creek County).

Mosquito district.—The London Mines & Milling Co. continued in 1941 to be the principal producer of gold, silver, copper, and lead in the Mosquito district and in Park County. The company owns and operates a consolidated group of mines on London Mountain opened by a 4,400-foot tunnel. The ore is treated in the company 200-ton flotation- and gravity-concentration mill near the portal of the tunnel. The concentrates produced contain chiefly gold, with some silver, a little copper, and considerable lead and zinc; they are sold to the Leadville smelter. The London-Butte Gold Mines Co. operated its Butte mine and 100-ton flotation mill throughout the year. The 150-ton Record mill was purchased by James N. Redman, trustee, from the London Extension Mining Co. on May 10, 1941; it was operated after July 23 and treated a total of 14,613 tons of ore, of which 2,143 tons came from the American mine, 11,679 tons from the London Extension reject dump, 476 tons from the South London dump, and 315 tons from the Record mill dump. Small lots of ore were shipped to the Leadville smelter from the Orphan Boy and Susquehanna mines.

Tarryall district.—The large increase in gold output from the Tarryall district in 1941 came from the Peabody-Volz group of placer mines

on Tarryall Creek 2 miles north of Como. The ground was leased in 1940 by Cooley Bros., *who installed a 3,000-cubic yard (per day) drag-*line floating dredge on the property during the first part of 1941 and operated it from May 4 to December 4. The Sterling Mining Co. operated its 1½-cubic yard dragline and four-bowl land dredge on the Little Mint-Storming Jordan placer on Tarryall Creek about 7 miles below Como during September and October. Gale L. Odell worked the Roberts placer on Tarryall Creek 2½ miles northwest of Como from June 15 to November 10 with a 1½-cubic yard dragline and screening and sluicing plant on wheels. Other placers on Tarryall Creek were worked by hand methods. A small output of gold and silver was made from the Stormchild and King Solomon-Pikes Peak lode properties.

PITKIN COUNTY

Roaring Fork district (Aspen).—The Midnight Mining Co. operated its Midnight mine and flotation mill continuously 6 days a week in 1941. The mill had a daily capacity of 60 tons, but the company had machinery on hand at the end of the year to raise the capacity to 75 tons or more. Ore treated in 1941 totaled 7,500 tons. The mill produced lead-silver concentrates, which were sold to the Leadville smelter, and zinc concentrates, which were shipped to the Amarillo (Tex.) zinc smelter. D. P. Rohlfing continued to ship to the Leadville smelter lime fluxing material carrying silver and lead from the Smuggler, Spar Consolidated, and other groups under his management. A lessee of the Hunter Creek flotation mill shipped a small tonnage of lead-silver concentrates recovered in the milling of silver- and lead-bearing dump material. A few tons of smelting ore were shipped from the Enigma and Unexpected claims.

RIO GRANDE COUNTY

Summitville district.—Gold production in the Summitville district, only producing district in Rio Grande County in 1941, increased 34 percent over 1940. All the output in both years came from the group of mines operated by Summitville Consolidated Mines, Inc. In 1941 the company treated a daily average of 83 wet tons of ore, 7 days a week, in its 150-ton mill at Summitville. In treatment the ore is ground in a ball mill with cyanide solution to minus-100-mesh. A jig between the ball mill and classifier removes coarse high-grade gold-silver-pyrite concentrates, which are shipped to the Leadville smelter. The classifier overflow goes to primary thickeners to remove pregnant solution; the primary thickener underflow goes to agitators and from them to three stages of countercurrent decantation. The pregnant solution is precipitated in Merrill-Crowe units, and the precipitates are acid-treated and reduced to bullion for shipment to the Denver Mint. During the year the company also carried on developing and prospecting work within the mine area on a deposit containing copper which previously had been avoided.

ROUTT COUNTY

Individuals recovered some gold and silver in 1941 from placers in the Hahns Peak area.

SAGUACHE COUNTY

Kerber Creek district (Bonanza).—Lessees at the Rawley group continued in 1941 to ship lead-silver-copper ore to smelters. The Flagstaff Mining & Milling Co. made intermittent test runs in its 50-ton flotation mill on ores from several properties. The ore treated included 205 tons of zinc-lead ore, which yielded 51 tons of zinc concentrates sold to the Ozark Smelting & Mining Co. plant at Coffeyville, Kans., and 10 tons of lead concentrates shipped to the Leadville smelter. Lessees on the Rawley No. 3 mine shipped some zinc-lead-silver-copper ore to the custom concentrator at Midvale, Utah. Other shippers of direct-smelting ore included the Liberty mine, Minnie Lynch, and Rico.

Myers Creek district.—The owners of the Silver Dollar claim shipped 1 ton of lead-silver ore to the Leadville smelter in 1941.

SAN JUAN COUNTY

Animas district.—Throughout 1941 the Shenandoah-Dives Mining Co. operated its consolidated group of claims on King Solomon Mountain (opened by the Mayflower tunnel) and 750-ton selective-flotation mill on Animas River near Silverton. The mill treated 231,519 tons of ore from company mines and 3,995 tons from other mines in San Juan and Ouray Counties. Output from the mill totaled 7,044 tons of combined lead-copper, zinc, and iron (lead) concentrates, containing in all 15,398 ounces of gold, 336,034 ounces of silver, 951,813 pounds of copper (wet assay), 3,443,741 pounds of lead (wet assay), and 2,161,931 pounds of zinc; the lead-copper and iron (lead) concentrates were shipped to the Leadville smelter, and the zinc concentrates (1,376 tons of 56.7 percent zinc content, with also gold, silver, and minor lead and copper content) to the Amarillo (Tex.) smelter. The bulk of the custom ore came from the Silver Lake mine of the American Smelting & Refining Co., worked through a 3,000-foot crosscut from inside the Mayflower tunnel. The rest came largely from the Coming Wonder and Little Fannie mines in the Animas district; the Esmeralda, Lead Carbonate, and Mountain Queen in the Eureka district, San Jaun County; and the Bachelor in the Uncompahgre district, Ouray County. Highland Mary Mines, Inc., operated the Highland Mary mine and 70-ton flotation mill from June 1 to December 5, 1941. The concentrates produced (containing gold, silver, copper, and lead) were shipped to the Leadville smelter. The Pride of the West Mining Co. operated its 70-ton selective-flotation mill continuously on company lead-zinc-gold-silver-copper ore from the Pride of the West group. Nearly 90 percent of the mill product was lead concentrates (containing gold, silver, copper, and some zinc) shipped to the Leadville smelter; the rest was zinc concentrates shipped to the Amarillo (Tex.) smelter. On January 9, 1942, a fire which destroyed the buildings at the portal of the mine closed it until May 17. Some ore was shipped direct to the Leadville smelter in 1941 from the Crusader, Golden Eagle, and other mines in the Animas district.

Eureka district.—Most of the ore produced from mines in the Eureka district in 1941 was sold to the Shenandoah-Dives mill (see Animas district). About 1 car of high-grade gold-silver ore was shipped to

the Leadville smelter from the Brooklyn mine. The Treasure Mountain Gold Mining Co. erected a 25-ton flotation mill at the portal of the Sandiago tunnel and treated 377 tons of gold-silver ore from the Golden Fleece dump. The Sunnyside mine and 1,000-ton selective-flotation mill at Eureka, closed June 30, 1938, remained idle throughout 1941.

Ice Lake Basin district.—The only output from the Ice Lake Basin district in 1941 was 19 tons of zinc-lead ore shipped to the Midvale (Utah) custom mill.

SAN MIGUEL COUNTY

Iron Springs district (Ophir).—Nearly all the metal output from the Iron Springs district in 1941 was contained in small tonnages of ore shipped to the Leadville smelter from the Carbonero, Hattie, New Dominion, San Bernardo, Sulphurette, Texas, and Yellow Jacket properties. The Butterfly mill at Ophir was destroyed by fire December 6, 1940; the Butterfly-Terrible-Silver Bell group had no output in 1941.

Lower San Miguel district (Sawpit, Vanadium).—Sluicing on San Miguel River 5 miles from Norwood recovered 7 ounces of gold and 3 ounces of silver in 1941.

Mount Wilson district.—A little high-grade gold ore was shipped from the Silver Pick mine in 1941, and about 3 ounces of gold were produced from another property in the Mount Wilson district.

Upper San Miguel district (Telluride).—Veta Mines, Inc., operated its amalgamation and gravity- and flotation-concentration mill at Pandora 2½ miles east of Telluride at an average rate of 532 tons daily for 365 days in 1941 compared with 486 tons in 1940. The company ore treated in 1941 (193,768 tons) came from the Smuggler Union, Cimarron, and Montana mines and the Smuggler, Cimarron, and Tomboy dumps; the custom ore (315 tons) came from the Pike County mine and the Tomboy dumps. About one-third of the gold output from the mill was recovered in gold-silver bullion and the rest in concentrates, which also contained the bulk of the recoverable silver and all the recoverable lead. The bullion was shipped to the Denver Mint and the concentrates to the Leadville smelter. Alta Mines, Inc., operated the Alta-St. Louis group and 150-ton gravity- and flotation-concentration mill throughout 1941 and produced 40,498 tons of ore yielding 3,185 tons of concentrates containing 2,546 ounces of gold, 115,330 ounces of silver, 95,774 pounds of copper, 1,032,178 pounds of lead, and 463,245 pounds of zinc; the concentrates were shipped to the Leadville smelter. Individuals working small mines and prospects in the Upper San Miguel district recovered some gold from high-grade ore reduced by hand methods.

SUMMIT COUNTY

Breckenridge district.—Small-scale operations only were carried on at lode mines in the Breckenridge district in 1941, and most of the ore produced was shipped direct to the Leadville smelter. A car of zinc ore from the Royal Tiger property was shipped to the Ozark Smelting & Mining Co. smelter at Coffeyville, Kans., and some zinc-bearing material from the Sally Barber dump was shipped to a custom mill at Idaho Springs (Clear Creek County). Producers of more than 25

tons of ore shipped to the Leadville smelter were the Bemrose lode, Carbonate, Dunkin, Fredonia, and Minnie B.

The leading producing placer mines in the Breckenridge district, some of which were equipped with small land dredges, were the Bemrose-Bostwick, Blue Beach, Ford and Bedrock, Long Island (worked by hydraulicking), Louis D, and Van Winkle.

Montezuma district.—G. W. Goodman continued in 1941 to work the Bullion group under lease from the Golden Cycle Corporation. Most of the time was spent in driving development drifts and putting in chutes in preparation for stoping. The mine is equipped with a 75-ton gravity- and flotation-concentration mill. About 180 tons of ore were treated during the year, yielding 44 tons of lead-copper-silver concentrates shipped to the Leadville smelter. The Plymouth Milling Co. worked throughout the year at the New York, Waterloo, and Silver King mines, reopening old tunnels and installing tracks, air pipes, and other equipment needed for mining. The company also built a 125-ton electric-powered selective-flotation mill. The mill was run intermittently for testing ores from August to December and treated 1,127 tons yielding 108 tons of lead-silver-copper-gold concentrates, shipped to the Leadville smelter, and 49 tons of zinc concentrates, sold to smelters at Coffeyville, Kans., and Amarillo, Tex. A small tonnage of lead-silver ore was treated in the 24-ton mill at the Marlin group. The 150-ton mill on the Pennsylvania property was remodeled to treat zinc and lead ores by flotation; the mine was not operated during the year. The Erickson, Florado, and Foremost mines shipped lead-silver ore to the Leadville smelter.

Ten Mile (Kokomo, Robinson) district.—Lessees at the Washington and Hancock mines (known as the Lucky Strike group) shipped 766 tons of zinc-lead-silver ore to the Midvale (Utah) custom concentrator in 1941. The Wilfley Leasing Co. installed flotation equipment in the Wilfley mill and made test runs on ore from the Wilfley mine; 12 tons of concentrates containing 4.70 ounces of gold, 201 ounces of silver, 4,760 pounds of lead, and 1,214 pounds of zinc were produced. Shippers of direct-smelting ore included the Leopard, Polar Star, Sammy B, and Silver Queen mines.

Wilkinson, Rock Creek, and Green Mountain district.—Walter McDaniel continued producing rich zinc-silver-lead-gold-copper ore from his Big Four mine on Green Mountain; the ore was shipped to the Midvale (Utah) custom mill. The mine is opened by a 760-foot tunnel with a 325-foot drift from a point 400 feet within the tunnel. Output in 1941 was 752 tons of ore containing 627,501 pounds of zinc, 23,637 ounces of silver, 58,941 pounds of lead, 20.5 ounces of gold, and 3,509 pounds of copper. Small tonnages of lead-silver-gold ore were shipped to the Leadville smelter from the Boss-Thunderbolt, Chief Mountain, and another property in the Wilkinson district.

TELLER COUNTY

CRIPPLE CREEK DISTRICT

Cripple Creek is the leading gold-producing district in Colorado. From 1891, when gold was discovered in that area, through 1941 it has yielded a total of 18,316,289 fine ounces valued at $394,644,597, or 48 percent of the State total output of gold from 1858 to 1941, inclusive.

In 1941 the district produced 133,470 ounces (35 percent of the State total) compared with 128,932 ounces (35 percent) in 1940 and 134,003 ounces (37 percent) in 1939. The increase in output in 1941 resulted from completion of the 6-mile Carlton drainage tunnel, permitting resumption of mining on the lower levels of the Ajax and Cresson mines. Details of work done during the year on the Carlton tunnel are given in the following Mines Review. The total output of ore from Cripple Creek mines and dumps in 1941 was 528,641 tons, of which 484,702 tons were shipped to the Golden Cycle mill (operations reviewed under El Paso County). Ore milled locally included 34,053 tons treated by flotation in the Cameron mill and 8,885 tons treated by cyanide leaching in the Kavanaugh plant. Cripple Creek ores generally contain gold as the only commercial metal, but some silver ore has been shipped from two or three veins in the district; a small quantity of silver is recovered annually in bullion and concentrates produced from the gold ores.

MINES REVIEW

Operations of the Golden Cycle Corporation, which owns and operates the Golden Cycle mill at Colorado Springs and several mines in the Cripple Creek district, are described in the following extract from its annual report to stockholders for the year ended December 31, 1941 (dated March 1, 1942):

In spite of adverse economic conditions existing in the gold-mining industry, the Cripple Creek district shipped to the Golden Cycle mill 484,702 tons with a [settlement] gross value of $4,640,419.99 and an average value of $9.57 per ton. This compares with 485,155 tons with a [settlement] gross value of $4,394,533.57 and an average value of $9.06 per ton for 1940 This increase in value was partly due to ore coming from the lower levels of the Ajax shaft of the Golden Cycle Corporation, which was completely drained by the Carlton tunnel in February 1941. All the lower levels of the Ajax were under water during the year 1940.

As in previous years, the United Gold Mines Co. and the Cresson Consolidated Gold Mining & Milling Co. were the largest shippers to the mill, with the Golden Cycle Corporation mining operations third. These three companies accounted for 66 percent of the ore. Lessees working on all properties in the district accounted for 83 percent of all the ore shipped from the Cripple Creek district, and all properties are dependent upon the lessees for the greater part of their tonnage.

Carlton tunnel.—The Carlton tunnel was finished to the breccia granite contact under the Portland in September 1941. 6,293 feet of tunnel was driven in 1941. From July 18, 1939, to September 1, 1941, a total of 32,927 feet or 6.236 miles of tunnel was driven. The daily average was 46.9 feet. The last 4,000 feet of tunnel were driven under extremely difficult conditions, due to the heavy flows of water encountered. The first water cut in the tunnel was on February 18, 1941, when the New Market fault in Ajax was reached. The flow of water at this time amounted to 25,000 gallons per minute. Work in the tunnel was suspended for about 10 days until the water subsided to about 10,000 gallons per minute. It was then necessary to drop back about 200 feet from the face and change the course of the tunnel, in order to cut the fault in a different place It was necessary to timber about 150 feet of heavy ground through the fault. From this point on, the tunnel was driven to the Portland without any great difficulty except heavy flows of water.

It was expected, when the breccia granite contact was reached, that enough water would be cut to quickly drain the Portland mine workings. 800 feet of water stood in the Portland shaft at this time. Due to the tight ground only a small flow of water was opened, which did not give rapid enough drainage. It was then necessary to drive a 125-foot raise from the tunnel, and from the top of the raise run a short crosscut toward the winze level of the Portland No. 2 shaft and drain the Portland workings in this manner. When this water was released the tunnel

flow increased to about 125,000 gallons per minute for a few hours, gradually subsiding to 6,000 gallons per minute. The heavy flow of water caused considerable damage in the tunnel, washing out track in several places and leaving considerable debris which was carried in from the Portland workings. This, however, has all been cleaned up and the tunnel is now in good shape.

Ajax operations.—Lessees and the dump, which the company was washing and sorting, furnished all the production for the Ajax until the Carlton tunnel drained the mine in February 1941. When the tunnel cut the New Market fault, the mine drained in 10 days time. Clean-up and repair work was started at once and within 2 months ore from the lower levels was being shipped to the mill. Production the latter part of the year was much greater than the first part, and the mine showed a profit instead of a loss. Company and lessees shipped 29,332 tons with a gross value of $437,760.05 and an average value of $14.92 per ton. This is above the average grade of ore shipped from the district and compares with 22,203 tons with a gross value of $226,628.07 and an average value of $10.21 per ton for the year 1940.

Development work opened ore on both the New Market and Bobtail vein systems on the 24th and 26th levels, and several drifts are now being driven on ore in different parts of the mine. Shaft sinking which is now in progress will open two new levels, the 27th and 28th. Crosscutting and drifting for the various vein systems will start on these new levels as fast as conditions permit.

Index operation.—During the first 10 months of 1941, the Index was operated by the company mainly for the accommodation of split-check lessees. The company, however, accomplished considerable development work and opened a number of small ore chutes, none of which were large enough to mine and make any money. It was decided to close the mine down on November 1, 1941, after the number of lessees dwindled to one set. A total of 1,662.5 feet of development work was done on the property during the year.

Anchoria Leland operation.—Development work on this property totaled 1,848 feet, of which the company accomplished 720 feet and the lessees 1,128 feet. Production amounted to 9,228 tons with a gross value of $92,956.30 and an average value of $10.07 per ton. Operations showed a loss for the year after depletion of $4,224.71.

Development work is still continued on this property mainly by lessees, and it is hoped that sufficient ore will be opened to operate the mine at a profit.

The annual report of the United Gold Mines Co., an operating and holding company for property scattered throughout the Cripple Creek district, for the year ended December 31, 1941 (dated February 15, 1942), gives the following details on operations at individual mines:

Production by company and lessees was 149,235.80 tons, with a gross value of $1,430,199.42 and an average value of $9.58. Lessees produced 92.7 percent of the tonnage and 95.5 percent of the gross value of the ore shipped. The Portland No. 1 and No. 2, Rose Nicol, Vindicator, Hull City, and Theresa shafts were operated on company account mainly for the accommodation of split-check lessees. Due to the present national emergency, a severe shortage of labor and lessees exists in the Cripple Creek district. The number of lessees working on the various United Gold Mines Co. properties has dropped off very greatly during the latter part of the year. We now have 42 sets of split-check lessees, 13 sets of royalty lessees, and 21 sets of dump lessees.

Portland group.—Both the Portland No. 1 and No. 2 shafts were operated on company account during the year, No. 1 shaft entirely for the accommodation of split-check lessees. These lessees produced a substantial tonnage of a good grade of ore. Portland No. 2 shaft has now become the main operation, due to its drainage by the Carlton tunnel. Shaft repairs and clean-up work was carried out on the 23rd, 24th, 26th, 27th, 29th, and 30th levels. Pipe lines and track are being installed in order to make as much of the mine accessible for work as possible. It is planned to do some development work on these levels, provided we can secure the necessary labor and material.

The company has been carrying on a development program throughout the year on the 17th level in Rose Nicol territory. In the course of this work the Trail basalt blow-out, which was mined on the Rose Nicol, was cut and found to be a fair grade of ore. Stoping will be started on this as soon as an air connection can be made with the 14th level of the Cresson mine.

Rose Nicol.—The company mined and shipped 7,467.20 tons of ore, with a value of $6.38 per ton, and the lessees shipped 9,443.74 tons with an average value of $13.67, or a total of 16,910.94 tons with a gross value of $176,725.99.

No production was made from Rose Nicol ground through the Cresson shaft during the past year, as the Cresson Co. was not able to handle the extra tonnage.

Vindicator group.—The Vindicator made a very good production during the past year. It produced 34,628.20 tons, with a gross value of $380.062.51. An average of 18 sets of lessees was active, employing about 55 men. The Theresa and Hull City shafts were steady producers throughout the year. Some company development work was done on the Theresa shaft. A new ore house was constructed at the Hull City at a cost of $1,800.00.

Shurtloff & Findley.—This property is under lease to the Golden Conqueror Mines, Inc., and is being worked through the South Burns shaft of the Acacia Gold Mines Co. A steady production was maintained during 1941, and a large amount of development work was also accomplished.

Wild Horse group.—The Wild Horse shaft was in operation during part of 1941. Some low-grade ore was shipped, but it was of such muddy, sticky character that the mill could not handle it and the mine was forced to close. The Gleason shaft of the Wild Horse was under lease to Dwyer Brothers and produced a smal tonnage of ore.

Patti Rosa.—This is under lease to the Tennessee Mines Co., who were steady shippers during the year. The Patti Rosa shaft was repaired and a skip installed to take the place of the bucket formerly used. This should speed up their production for 1942.

Deadwood.—This property is under lease to the Gold Bullion Mines, Inc., who maintained a steady production throughout the year.

Due to a safety program we have carried on for the past 3 years, our rate on compensation insurance has been cut from a high of $8.81 3 years ago to $6.198 for the year 1942.

Production of company ore by United Gold Mines Co. in 1941

Mine	Net tons	Gross value [1]	Company ore cash receipts	Average gross value ton [1]
Vindicator	1,513	$6,830 79	$2,293 83	$4.52

The annual report of the Cresson Consolidated Gold Mining & Milling Co. for the 12 months ended December 31, 1941 (dated January 15, 1942) says—

The following is a summary of the development work for the 12 months ending December 31, 1941:

Development

	Feet	Feet
Drifts and crosscuts:		
Company	2,495	
Hart group	708	
Lessees	1,506	
		4,709
Raises and winzes:		
Company	435	
Lessees	1,644	
		2,079
		6,788

Production during the year was maintained at full capacity of the plant. Development work was also continued on all blocks of undeveloped ground where it was felt an ore chute might be opened. Some bodies of ore were opened by the company on the 5th, 12th, 13th, and 16th levels. One large stope of low-grade ore is being mined by the company on the 16th level at the present time.

There are 30 sets of split-check lessees working through the Cresson shaft. These lessees made a very good production during the past year. One set of lessees, working on the 10th level, opened up and shipped some very high-grade ore.

The Gold Sovereign shaft is under lease to F. G. Blackwood & Co., and produced a considerable tonnage of low-grade ore.

The Carlton tunnel, driven by the Golden Cycle Corporation, was completed to the Portland No. 2 shaft, and a raise completed through to the 31st level. Preparations are now under way to connect the Portland No. 2 shaft with the tunnel level.

The first large flow of water was cut in the tunnel about the middle of February 1941, and drainage of the southern part of the district began almost immediately. The tunnel is now making 6,000 gallons per minute, although at one time a flow in excess of 100,000 gallons per minute was encountered. The water level in the Cresson shaft has been lowered 240 feet since the middle of February. The 19th level, which is 250 feet below the Roosevelt tunnel, is now dry, and clean-up work on this level is under way. There are several drives to be made on this level, and it is felt that some ore will be opened.

While the rate of drainage at the Cresson shaft was at first rapid, the rate of drainage at the present time is slowing down. It will be over a year before the 20th level, which is 125 feet below the 19th level, is unwatered. For this reason, it will be necessary for the Cresson Co. to drive a 4,000-foot lateral from the main Carlton tunnel into Cresson ground, in order to obtain drainage at a rate fast enough to keep the necessary development work ahead of mining. The Cresson might eventually drain almost to the same level as the Carlton tunnel, but it would require a great many years. It would not allow us to open up the ground below the level we are now working, nor drain at a fast enough rate to keep the mine going.

The lateral from the main Carlton tunnel to the Cresson will be about 4,000 feet in length. Approximately two-thirds of the distance will be through ground owned by the United Gold Mines Co. The remaining distance will be through Cresson ground. Arrangements for a lease on the ground belonging to the United Gold Mines Co., through which the tunnel will pass, have been made; so the Cresson Co. will be protected on any ore this lateral might open. This work will be started as soon as the Portland shaft is completed to the Roosevelt tunnel level. Arrangements have been made to use the tunnel equipment owned by the Golden Cycle Corporation for this work.

Economic conditions caused by the war are beginning to be felt very severely. A shortage of labor and lessees exists throughout the Cripple Creek district and is getting worse as time goes on. Men are naturally attracted by the much higher wages paid by defense industries. A raise in wages, amounting to about 8½ percent, was made by the mines 3 months ago; but with this raise wages here are below all Government work. The price of most mining supplies has raised during the past year.

Compensation insurance costs decreased again this year to a new low of $4.057 per $100 of pay roll. This is the lowest rate in the Cripple Creek district.

The average operating cost per ton shipped by company and the lessees during 1941 was $2.880 on a total of 130,166 tons.

1903 to Dec. 31, 1941			14.61	9 81	[2] 13,479,272.50

[1] Settlement value.
[2] Represents 29.84 percent of gross value and 44.42 percent of net value.

Shipments from the Stratton properties in 1941 totaled 28,738 tons of mine ore and 15,113 tons of dump, which together had a total gross settlement value of $416,305.78 or an average settlement value of $9.49 per ton. Most of the ore was mined by lessees under the royalty system. The bulk of the dump ore was shipped by the Regain Corporation from three groups of dumps on Bull Hill. The principal producers of mine ore were the Alie Bell Mining Co. (Proper mine), C. E. Sullivan and Longfellow Mining Co., A. S. Cobb, and J. E. Van Dewalker.

Cameron Gold Mines, Inc., operated its group of mines and 100-ton flotation mill continuously in 1941. Ore treated totaled 34,053 tons yielding 1,503 tons of concentrates containing 5,038 ounces of gold and 2,910 ounces of silver; the concentrates were shipped to the Leadville smelter. The mill feed included 1,072 tons of custom ore milled for the Tenderfoot Mining Co. Thomas Kavanaugh operated his Iron Clad group and cyanide plant 6 months during the year, treating 8,885 tons of ore yielding 504 fine ounces of gold and 77 fine ounces of silver. In approximate order of gold output, the Empire Lee, Free Coinage, El Paso, Acacia, Dr. Jack Pot, Jerry Johnson, Mary Nevin, and Mary McKinney continued to be important producers in 1941. Some of the other producing mines and dumps were the Atlas, Black Belle, Buckeye, Cardinal-Great West, Delmonico, Economic dump, Joe Dandy, Nellie V and War Eagle, New Gold Dollar, and Strong.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN THE EASTERN STATES

(MINE REPORT)

By A. J. Martin

SUMMARY OUTLINE

The mine output of recoverable gold, silver, copper, lead, and zinc in the Eastern States in 1941 was valued at $34,159,265—$5,941,270 more than in 1940 and the highest value in any year since 1917. Zinc represented 86 percent of the total in both 1941 and 1940 and 85 percent in 1917. Mine shipments of zinc in 1941 increased 7 percent over 1940 and set a new annual record. Gains in production and shipments were made in New Jersey, New York, and Tennessee; in Virginia actual production of both zinc and lead during the year was less than in 1940,but the quantities shipped (production credited to year of shipment in the tables that follow) were larger. Lead production increased in New York and decreased in Tennessee. The output of copper, nearly all of which came from North Carolina, Pennsylvania, and Tennessee, increased 6 percent over 1940. Gold production rose 19 percent and was the highest in both quantity and value since 1882. The principal gold-producing States were South Carolina, North Carolina, and Pennsylvania. The silver output was recovered from the refining of the gold, copper, and lead produced.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0 7735	$0 121	$0 059	$0 065
1938	35 00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052
1940	35 00	[6] .711+	.113	.050	.063
1941	35 00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31,1934, was $20.67+($20 671835) per fine ounce.
[2] 1937. Yearly average weighted Treasury buying price for newly mined silver, 1938–41· Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464.
[5] $0.67878787.
[6] $0.71111111.

Annual figures for the 5 years ended with 1941 are given in the table that follows. The figures for tonnage of ore sold or treated do not include magnetite ore containing pyrite and chalcopyrite, from which copper, gold, and silver were recovered as byproducts.

Mine production of gold, silver, copper, lead, and zinc in the Eastern States, 1937–41, in terms of recovered metals

Year	Mines producing		Ore sold or treated (short tons) [1]	Gold (lode and placer) [2]		Silver (lode and placer) [3]	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1937	39	40	3,407,883	10,680.90	$373,832	106,873	$82,667
1938	51	26	3,159,880	19,928.00	697,480	94,945	61,380
1939	47	24	3,409,619	17,414.00	609,490	94,083	63,862
1940	40	18	3,674,815	18,456.00	645,960	102,825	73,120
1941	43	14	3,780,397	21,982.00	769,370	106,051	75,414

Year	Copper		Lead		Zinc		Total value
	Pounds	Value	Short tons	Value	Short tons	Value	
1937	24,444,000	$2,957,725	5,539	$653,602	189,353	$24,894,159	$28,961,985
1938	21,079,160	2,065,758	7,900	726,800	172,501	19,211,235	22,762,653
1939	21,295,000	2,214,680	6,284	590,696	180,955	21,100,174	24,578,902
1940	25,490,000	2,880,370	4,831	483,100	178,815	24,135,445	28,217,995
1941	27,132,000	3,201,576	5,513	628,482	191,310	29,484,423	34,159,265

[1] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.
[2] Includes placer gold as follows 1937, 632 ounces; 1938, 667 ounces; 1939, 413 ounces, 1940, 452 ounces; 1941, 203 ounces
[3] Placer silver did not exceed 39 ounces in any year during the 5-year period.

Gold. The old Haile mine in Lancaster County, S. C., near Kershaw, yielded 69 percent of the total mine output of gold in the Eastern States in 1941. Other substantial producers were the Condor (old Howie) mine near Waxhaw, Union County, N. C.; and the Cornwall mine in Lebanon County, Pa., which yields gold, silver, and copper as a byproduct of iron mining. Changes in output of gold in the various States in 1941 comprised increases of 2,432 ounces in South Carolina, 1,301 ounces in North Carolina, 582 ounces in Pennsylvania, 54 ounces in Tennessee, and 25 ounces in Alabama; and decreases of 650 ounces in Georgia and 218 ounces in Virginia. The estimated output of gold in the Southern Appalachian States from 1799 to 1941 is recorded as follows:

Mine production of gold in the Southern Appalachian States, 1799–1941

State	Period	Fine ounces	Value	State	Period	Fine ounces	Value
Alabama	1830–1941	49,488	$1,198,740	South Carolina	1829–1941	310,830	$7,283,140
Georgia	1830–1941	870,479	18,082,612	Tennessee	1831–1941	20,038	448,960
Maryland	([1])–1941	6,102	163,940	Virginia	1828–1941	167,255	3,566,904
North Carolina	1799–1941	1,160,359	24,179,828	Total	1799–1941	2,584,551	54,924,124

[1] Year of first production not recorded.

Silver.—The silver recovered from ores and gravels mined in the Eastern States in 1941 totaled 106,051 fine ounces—59,221 ounces derived from copper and iron (magnetite-pyrite-chalcopyrite) ores, 37,734 ounces from zinc-lead ores, 9,081 ounces from gold ores, and 15 ounces from placer gravel.

Copper.—As the three mines that produced nearly all the copper output of the Eastern States in 1941 are in different States (North Carolina, Pennsylvania, and Tennessee), it is not possible to show the production separately by States without disclosing that of each mine; the combined output of the three States is shown under Tennessee in the following table. The total Eastern States production rose from 25,490,000 pounds in 1940 to 27,132,000 pounds in 1941. Gold ore from South Carolina and North Carolina yielded 1,265 pounds of copper. Copper ore yielded, in recovered metals, about 0.0004 ounce of gold and 0.06 ounce of silver to the ton of crude ore. Copper concentrates from the magnetite-pyrite-chalcopyrite ore of the Cornwall mine in Pennsylvania contained some recoverable gold and silver.

Lead.—The recoverable lead in concentrates shipped from mines in the Eastern States totaled 5,513 tons in 1941, an increase of 682 tons over 1940. The figures include some concentrates that were stock-piled at the mine in previous years and are credited to production for 1941, the year of shipment. Zinc-lead sulfide ores from the Austinville mine in Virginia and the Balmat in New York yielded all the lead output except 23 tons derived from lead carbonate and zinc-lead sulfide ores from Tennessee.

Zinc.—The mine output (shipments) of recoverable zinc in the Eastern States was 191,310 tons in 1941, an increase of 12,495 tons over 1940. New Jersey contributed 49 percent of the total in 1941, New York 20 percent, Tennessee 19 percent, and Virginia 12 percent. The Virginia shipments include a substantial tonnage of concentrates from mine stocks carried over from previous years. The newly developed Hyatt mine near Emeryville, N. Y., which began producing on a small scale in February 1941, and the Jarnagin mine at Jefferson City, Tenn., reopened in April, contributed part of the 7-percent increase in total output from the Eastern States during the year. Zinc ore yielded 73 percent of the total zinc output and zinc-lead ore and copper ore together 27 percent. The proximity of the large zinc mines of the Eastern States to smelting and manufacturing centers enhances their importance as a source of zinc in time of war, when transportation becomes a material factor in obtaining supplies. Statements furnished by mine operators early in December 1941 indicated an increase in production from their mines for 1942. The Government premium-price program announced January 12, 1942, provides an incentive for increasing the output from established mines and reopening marginal properties, and it may cause a larger gain.

MINE PRODUCTION BY STATES

Mine production of gold, silver, copper, lead, and zinc in the Eastern States in 1941, by States, in terms of recovered metals

State	Mines producing		Ore (short tons)	Gold			Silver		
				Fine ounces		Total value	Fine ounces		Total value
	Lode	Placer		Lode	Placer		Lode	Placer

[1] Ore is magnetite-pyrite-chalcopyrite, flotation copper concentrates from which yielded gold, silver and copper; Bureau of Mines not at liberty to publish figures for ore and copper.
[2] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.
[3] Estimated smelting value of recoverable zinc content of ore after freight, haulage, smelting, and manufacturing charges are added.
[4] North Carolina and Pennsylvania included under Tennessee; Bureau of Mines not at liberty to publish separate figures.
[5] Excludes value of copper, which is included under Tennessee.
[6] Includes also value of copper from North Carolina and Pennsylvania.

MINING INDUSTRY

The total output of ores yielding gold, silver, copper, lead, or zinc in the Eastern States in 1941, excluding the magnetite-pyrite-chalcopyrite ore from Pennsylvania, was 3,780,397 tons—a 3-percent increase over 1940. The quantity of gold-bearing sand and gravel handled at placer mines in the Southern Appalachian region was small; the Ferey Mining Co., only operator that reported using mechanical equipment in placer mining during the year, shut the equipment down in August after a few months of intermittent operation on the Barlow placer near Dahlonega, Ga. The gold ore output (most of which was treated by cyanidation) averaged $4.36 to the ton in gold and $0.04 in silver and copper. The copper, zinc, and

zinc-lead ores of the Eastern States yield byproducts (besides gold and silver), the value of which would have to be considered to show the full value of the crude ore mined. Copper-iron ore from Tennessee and zinc-lead-pyrite ore from New York yield pyrite concentrates that are used in the manufacture of sulfuric acid, and sulfuric acid is also made from gases produced in roasting zinc sulfide concentrates from zinc and zinc-lead ores of Tennessee, New York, and Virginia. New Jersey zinc ore yields a residue, which is further treated for the recovery of other metals; and zinc ore milled in Tennessee yields a commercial tailing, some of which is sold for its lime content and some for use in concrete. The quantity of the various types of ore mined in the Eastern States is shown in the table that follows.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in the Eastern States in 1941, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (short tons)	Zinc (short tons)
Dry and siliceous gold ore	152,833	19,033	9,081	1,265		
Copper ore	751,516	324	44,205	[1] 27,130,735		(2)
Magnetite-pyrite-chalcopyrite ore	(3)	2,422	15,016	(1)		
Lead ore	469				19	
Zinc ore	2,037,653					140,415
Zinc-lead ore	837,926		37,734		5,494	[2] 50,895
Total, lode mines	[4] 3,780,397	21,779	106,036	27,132,000	5,513	191,310
Total, placers		203	15

[2] Zinc from copper ore included with that from zinc-lead ore, Bureau of Mines not at liberty to publish separate figures
[3] Bureau of Mines not at liberty to publish separate figures for ore and copper.
[4] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.

METALLURGIC INDUSTRY

All the principal producing base-metal mines in the Eastern States except the Fontana copper mine in North Carolina have concentrating mills at or near the mines, but a considerable tonnage of copper ore is smelted direct and some of the crude zinc ore is shipped to oxide plants. The ore from the Fontana mine is shipped to the Tennessee Copper Co. plant in Tennessee. The methods of treatment used in the various mills and other operating details, including the tonnage and grade of concentrates produced by some of the mills, are given in the Review by States that follows. Most of the concentrates are shipped to smelters operated by the companies that own the mines. The methods of recovering the gold and silver are shown in the following table.

Mine production of gold and silver in the Eastern States in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)
Ore and old tailings amalgamated	3,348	418	173
Ore cyanided	149,123	18,323	8,831
Concentrates smelted [1]	75,778	2,649	91,911
Ore smelted [1]	19,764	389	5,121
Placer		203	15
		21,982	106,051
Total, 1940		18,456	102,825

[1] Excludes material containing no recoverable gold or silver. The totals for concentrates and direct-smelting ore shipped were 694,222 and 70,117 tons, respectively.

REVIEW BY STATES

ALABAMA

At the Hog Mountain mine near Alexander City, Tallapoosa County, 1,000 tons of old tailings from the mill dump were treated in 1941 by gravity concentration followed by amalgamation of the concentrates; the recovery was 28 fine ounces of gold and 3 fine ounces of silver. A lessee at the Gold Log mine near Talladega recovered 2 ounces of gold from about 20 tons of quartz treated by crushing, grinding, and amalgamation.

GEORGIA

Mines in Georgia yielded 311 fine ounces of gold and 38 fine ounces of silver in 1941, but no recoverable copper, compared with 961 ounces of gold, 630 ounces of silver, and 25,200 pounds of copper in 1940. The output in 1941 comprised 122 ounces of gold and 24 ounces of silver recovered from ore amalgamated at lode mines and 189 ounces of gold and 14 ounces of silver derived from placer gravel. The Ferey Mining Co. worked the Barlow placer near Dahlonega with a dragline and portable washing plant from March to August and produced about one-half of the State output of gold. Sluicing at small placers in Cherokee, Lumpkin, and White Counties recovered 32 ounces of gold. The Brand Estate claim in Cherokee County, the Findley and Lockhart mines in Lumpkin County, and the Russell mine in Paulding County were among the producing lode mines. All the Georgia output of gold and silver in 1941 was sold to the United States Mint at New Orleans, La. This mint discontinued purchasing newly mined gold and silver as of April 25, 1942.

NEW JERSEY

Zinc ore produced in New Jersey in 1941 totaled 585,463 tons containing 93,781 tons of recoverable zinc as metal or in oxide compared with 556,031 and 91,406 tons, respectively, in 1940. The producing mines were the Mine Hill at Franklin and the Sterling Hill at Ogdensburg, both in Sussex County. The ore bodies in these mines are unique in that they are said to be the only ones in the world from which all three of the minerals franklinite, willemite, and zincite are being mined in commercial quantities. The minerals, ore deposits, and mining methods are described in recent publications of the Geo-

logical Survey and the Bureau of Mines.[1] In the reduction of the ores the franklinite (an iron-manganese-zinc oxide mineral) is removed from the crushed ore by magnetic separators, and the willemite and zincite are concentrated on jigs and tables. The concentrates and some crude ore are shipped to smelters at Palmerton, Pa.

New Jersey has a few deposits of copper ore, but none has been worked for many years. At Carteret and Perth Amboy are copper and lead smelters and refineries that treat ores, scrap, byproducts, and bullion from various States and foreign countries.

NEW YORK

Zinc and zinc-lead ores mined in New York in 1941 yielded 38,446 tons of recoverable zinc, 2,100 tons of lead, and 37,734 fine ounces of silver—increases over 1940 of 2,760 tons in zinc, 127 tons in lead, and 2,014 ounces in silver. The producing mines in 1941 were the Balmat about 8 miles southeast of Gouverneur, the Edwards at the town of Edwards about 12 miles northeast of the Balmat, and the Hyatt near Emeryville, all in St. Lawrence County. The Balmat and Edwards mines are owned and operated by the St. Joseph Lead Co. The Balmat ore contains zinc, iron, and lead sulfides, and some silver is associated with the lead; it is mined through a 2,655-foot inclined shaft (vertical depth, about 1,300 feet) and treated in the selective flotation plant at the mine. The daily capacity of the mill at the end of 1941 was 1,100 tons. The mill feed in 1941 totaled 336,271 tons of ore; it yielded 3,578 tons of lead concentrates averaging 60.35 percent lead, 52,075 tons of zinc concentrates averaging 56.34 percent zinc, and 71,633 tons of pyrite concentrates averaging 41.35 percent iron and 49.39 percent sulfur. The lead concentrates contained considerable silver. The Edwards mine, which produces zinc ore, is opened by a vertical shaft to the 1,500-foot level and has an inclined shaft 1,212 feet long from this level to the lower workings. The mine is equipped with a 500-ton flotation mill, which treated 126,220 tons of ore yielding 21,421 tons of zinc concentrates averaging 58.71 percent zinc. The zinc concentrates from both mills were shipped to the company electrothermic zinc-reduction plant at Josephtown, Pa. The lead concentrates from the Balmat mill were shipped to the U. S. Metals Refining Co. plant at Carteret, N. J., and the pyrite concentrates were sold to sulfuric acid plants. The Hyatt zinc mine is owned by the Universal Exploration Co., which began developing it in 1938 and in 1940 nearly completed construction of a 200-ton flotation mill. The mill began treating ore early in 1941 and produced several cars of concentrates monthly from February through December; the concentrates were shipped to the Donora (Pa.) smelter.

NORTH CAROLINA

Gold production in North Carolina in 1941 totaled 3,244 fine ounces, and silver totaled 7,439 fine ounces, compared with 1,943 and 6,480 ounces, respectively, in 1940. Copper output from the Fontana

[1] Palache, Charles, The Minerals of Franklin and Sterling Hill, Sussex County, N. J.: Geol. Survey Prof Paper 180, 1935, 135 pp.
Jackson, Chas. F., Knaebel, John B., and Wright, C. A., Lead and Zinc Mining and Milling in the United States, Current Practices and Costs: Bureau of Mines Bull. 318, 1935, pp. 44, 134.

copper mine in Swain County—only producer of copper ore in the State during the year—varied little from that in 1940. The mine is operated by the North Carolina Exploration Co., which ships the crude ore to the Tennessee Copper Co. smelter at Copperhill, Tenn. The Fontana ore contains very small quantities of gold and silver, some of which are recovered as byproducts in refining the copper bullion. The Condor (old Howie) mine near Waxhaw in Union County, operated under lease by Hugh Jardine, was again the principal producer of gold in the State; milling of the ore at the Capps mill, Charlotte, was discontinued in January 1941, and a countercurrent cyanide mill was erected on the Condor property and operated continuously after July 15. Gold ore treated at this mill and copper ore from the Fontana mine yielded nearly all the silver output of the State during the year. A little gold was recovered from ore amalgamated at the Chapman property in Burke County and the Hoover Hill in Randolph County. A 28-ton lot of gold ore was shipped from a property near Ranger, Cherokee County, to the smelter at Copperhill. Small placers in Halifax and McDowell Counties yielded 6 fine ounces of gold and 1 fine ounce of silver.

PENNSYLVANIA

Gold, silver, and copper are recovered as byproducts of iron mining at the Cornwall mine of the Bethlehem Steel Co. in Lebanon County. The mine is developed by an open pit and three inclined shafts. The shafts were extended 200 feet during 1941 to a total depth of 1,500 feet. The ore contains magnetite, and pyrite and chalcopyrite carrying a little gold and silver; it is treated in the company plants at Lebanon, comprising a magnetic separation plant producing iron concentrates, a sintering plant for handling the iron concentrates, and a flotation mill in which the tailings from the magnetic plant are concentrated to recover copper, gold, and silver. The capacity of all three plants was expanded in 1941—that of the magnetic plant from 6,000 tons daily to 6,500 tons, the sintering plant from 2,000 to 2,400 tons, and the flotation plant from 2,500 to 2,800 tons. The rise in the production rate for iron resulted in an increase in the output of byproduct metals; the quantity of copper recovered rose 30 percent over 1940, gold 32 percent, and silver 15 percent.

SOUTH CAROLINA

In 1941, for the fifth consecutive year, South Carolina ranked first among the Eastern States in gold production. The old Haile mine in Lancaster County, 3½ miles northeast of Kershaw, continued to be the chief producer. The mine is equipped with a 400-ton cyanide plant, which was operated continuously in 1941. The ore is mainly quartz and pyrite; that produced in 1941 was mined from open pits. Ore treated during the year totaled 134,854 tons yielding 15,197 fine ounces of gold and 6,447 fine ounces of silver compared with 126,261 tons in 1940 yielding 12,861 ounces of gold and 7,970 ounces of silver. Other mines in the State yielded a total of 311 ounces of gold, 78 ounces of silver, and 1,000 pounds of copper in 1941. Small lots of gold were shipped to the Philadelphia Mint and the New York Assay Office from the Funder Bunk mine and the Mineral Mining Corporation properties in Lancaster County and the Oro at Pageland in

Chesterfield County. Crude ore containing gold and a little silver and copper was shipped from the Terry and Ross-Carroll mines near Smyrna, York County, to the U. S. Metals Refining Co. smelter at Carteret, N. J. W. K. Hunter, of Hickory Grove, shipped several cars of gold ore to the Tennessee Copper Co. smelter at Copperhill, Tenn.

TENNESSEE

The mine production of gold, silver, and zinc in Tennessee increased moderately in 1941 over 1940, copper decreased slightly, and lead declined sharply. The increase in zinc was the sixth in successive years, and the quantity produced (36,170 tons) was larger than in any previous year. The gold and silver and some of the zinc were byproducts of the copper-iron mining, milling, and smelting operations of the Tennessee Copper Co. at Ducktown and Copperhill in Polk County. Important commercial products derived from the copper-iron ores (besides copper bullion and zinc concentrates) included sulfuric acid and copper sulfate manufactured in the company plants and iron sinter sold to iron and steel producers, mostly in the Birmingham (Ala.) district. The zinc concentrates produced in the mills were sold to the Donora (Pa.) smelter. The new reverberatory furnace placed in operation at the company smelter in September 1940 was operated throughout 1941; the three blast furnaces formerly used for smelting were maintained as stand-by equipment. Most of the blister copper from the converter was cast into pigs and shipped to an electrolytic refinery on the Atlantic seaboard, where the byproduct gold and silver were recovered. Shot copper was produced for use at the copper sulfate plant. In 1941 the company operated the Burra Burra, Eureka, Isabella, and Boyd groups of mines and the London and Isabella selective flotation mills. The mines are opened by two vertical shafts 755 and 2,400 feet deep. Development work done during the year totaled 414 feet of shaft, 20,201 feet of drifts, and 28,077 feet of diamond drilling. The rated capacity of the London mill is 1,350 tons of ore daily and that of the Isabella 850 tons. In addition to crude ore and concentrates from company mines and mills the smelter treated considerable copper-iron sulfide ore from the Fontana mine in Swain County, N. C., and a small tonnage of gold ore from mines in North Carolina and South Carolina.

The principal zinc-producing mines in Tennessee in 1941 were the Mascot group in Knox County and the Grasselli, Jarnagin, and Davis groups in Jefferson County. The Jarnagin mine was reopened in April 1941 after having been closed since December 1937. The Mascot, Grasselli, and Jarnagin were operated by the American Zinc Co. of Tennessee, which concentrated the ore from all three mines in its Mascot mill. The mill is equipped with a differential-tension density unit, jigs, and flotation machines. In 1941 the mill treated 1,017,451 tons of ore yielding 44,537 tons of concentrates averaging 60.6 percent zinc. The Mascot mine is opened by a 520-foot shaft and an inclined shaft from the 520-foot level to the maximum depth of 850 feet. The Grasselli has one operating shaft and an auxiliary manway shaft and is 350 feet deep. Power-operated scrapers are used in both mines. The Jarnagin has one operating shaft 280 feet deep, with an auxiliary manway shaft. Development done in the three mines in 1941 totaled 355 feet of shaft, 5,763 feet of drifts, 7,325 feet

of diamond drilling, and 12,667 feet of churn drilling. The Davis group at Jefferson City is owned and operated by the Universal Exploration Co. The company 800-ton flotation mill for treating sulfide ore was operated at approximate capacity throughout 1941, and the 100-ton plant for concentrating carbonate ore was run at less than capacity from July to December. The average grade of the blende shipped in 1941 was 64.48 percent zinc. The Embree Iron Co., which owns properties in Washington and Unicoi Counties near Embreeville, operated its lead and zinc mines on a small scale from January to June, when production of these metals was suspended. In December the Imperial Mining Co. began operating the Imperial mine about 2 miles northwest of Goin, Claiborne County. The mill is equipped with a 4-cell jig. Production in 1941 was 35 tons of zinc-lead concentrates, shipped to the Ozark Smelting & Refining Co. plant at Coffeyville, Kans. Other output in the State in 1941 included a car of zinc ore from the Finchum property at New Market and a car of zinc concentrates shipped from Murfreesboro by an individual.

VIRGINIA

Virginia mines produced 240 fine ounces of gold and 135 fine ounces of silver in 1941 compared with 458 and 271 ounces, respectively, in 1940. No recoverable copper was produced in the State from 1939 to 1941, inclusive. The Red Bank mine near Virgilina, Halifax County, equipped with a small amalgamation mill, was the only lode mine in the State producing gold and silver in 1941; it was operated from January to July 18 by Joseph Hamme, owner, who then sold it to Red Bank Gold Mines, Inc., which made no output the rest of the year. A little gold was recovered from the Ruth placer in Goochland County.

The recoverable lead and zinc in concentrates shipped from Virginia in 1941 was 3,390 tons of lead and 22,913 tons of zinc, an increase of 1,105 and 5,986 tons, respectively, over 1940. A substantial part of the concentrates shipped in 1941 came from mine stocks accumulated in previous years. Actual mine production of both lead and zinc was less than in 1940. The Austinville zinc-lead mine of the New Jersey Zinc Co. in Wythe County, only large producer of lead and zinc in the State for many years, was operated continuously in 1941; it is equipped with a 2,000-ton flotation mill. The Lacy-Butler Co. shipped a car of zinc ore from a mine at Cripple Creek, Va.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN IDAHO

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

SUMMARY

The total value of gold, silver, copper, lead, and zinc produced by Idaho mines was $41,776,848 in 1941 compared with $37,744,393 in 1940—an increase of nearly 11 percent (see fig. 1). The quantity and total value of each metal except silver increased; the greatest gain was $2,966,874 in zinc. The value of the gold production represented nearly 13 percent of the State total, silver 28 percent, copper 2 percent, lead 29 percent, and zinc 28 percent. Production of gold in Idaho in 1941 (149,816 fine ounces) exceeded the 1940 production, which had been the largest since 1871, and the output of zinc (158,168,000 pounds) was by far the greatest in any year in the history of the State. Compared with 1940 the gold output increased 2 percent, copper 8 percent, lead less than one-half of 1 percent, and zinc 12 percent; silver declined 5 percent. The gain in gold output was due entirely to increased output from dredging at placer properties, as the output from lode mines decreased.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052
1940	35.00	[6] .711+	.113	.050	.063
1941	35.00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+ ($20.671835) per fine ounce.
[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938–41: Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Idaho, 1937–41, and total 1863–1941, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1937	347	741	2,075,402	81,861	$2,865,135	19,587,766	$15,151,137
1938	305	463	1,999,147	103,513	3,622,955	18,993,676	12,278,740
1939	362	465	2,108,445	116,662	4,083,170	17,222,370	11,690,336
1940	378	548	2,556,687	146,480	5,126,800	17,552,240	12,481,593
1941	331	524	2,704,680	149,816	5,243,560	16,672,410	11,855,936
1863–1941			(1)	7,629,158	170,159,933	469,574,957	322,200,087

Year	Copper		Lead		Zinc		Total value
	Pounds	Value	Pounds	Value	Pounds	Value	
1937	4,464,000	$540,144	207,422,000	$12,237,898	108,398,000	$7,045,870	$37,840,184
1938	4,278,000	419,244	184,354,000	8,480,284	88,060,000	4,226,880	29,028,103

1941	4,899	1,149	228	46	3,185	388	11,725	2,100	52,358	13,725	72,395	17,408

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline floating dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

Gold.—The output of recoverable gold in Idaho was 2 percent greater in 1941 than in 1940. The yield of gold from lode mines decreased 10 percent, and most of the loss was from gold ore; the production from placers increased 20 percent, owing to larger output from dredging. About 42 percent of the State total gold in 1941 came from siliceous gold ore and 45 percent from all types of dredging operations. Twelve floating (bucket) dredges, the same number as in 1940, treated 10,612,000 cubic yards of gravel and recovered 52,358 ounces of gold—an increase of 11,096 ounces over 1940; 9 dragline dredges and 12 dry-land dredges treated 2,342,000 cubic yards of gravel and recovered 14,910 ounces of gold—an increase of 2,718 ounces. Of the total placer gold, 84 percent came from the Boise Basin, Elk City, Yankee Fork, Warren, Hoodoo, Middle Boise, and Gibbonsville districts, where dredges were operated. Of the

total lode gold, 81 percent came from the Middle Boise, Yellow Pine, Warm Springs, Burgdorf-Marshall Lake, Carson, Yankee Fork, Mineral Hill, and West View districts and the Coeur d'Alene region. Substantial increases in output of gold were made in the Middle Boise, Yankee Fork, Elk City, Hoodoo, and Gibbonsville districts but large decreases in the Boise Basin and Yellow Pine districts and the Coeur d'Alene region.

Talache Mines, Inc., operating lode property at Atlanta, was again the largest gold producer in Idaho. It was followed by the Fisher-Baumhoff Co., which continued to operate two bucket dredges near Centerville; Yellow Pine mine at Stibnite; H. & H. bucket dredge near Elk City; Snake River Mining Co. (bucket dredge) at Sunbeam;

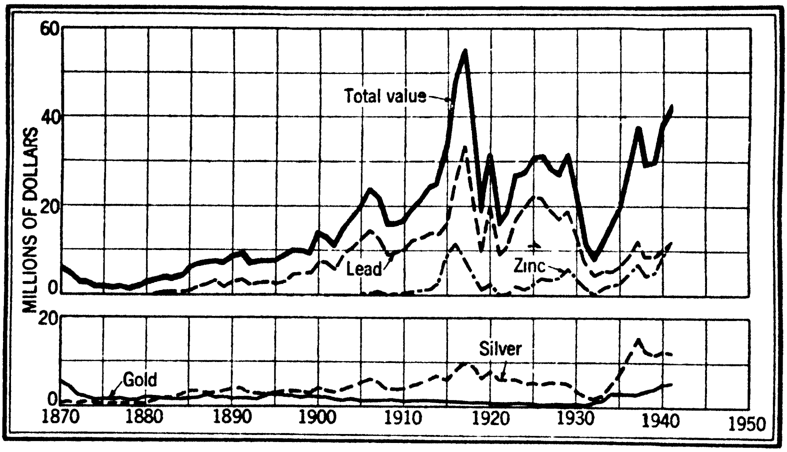

FIGURE 1 —Value of mine production of gold, silver, lead, and zinc and total value of gold, silver, copper, lead, and zinc in Idaho, 1870–1941 The value of copper has been less than $2,000,000 annually, except in a few years.

Golden Anchor mine at Burgdorf; Northwest Goldfields bucket dredge near Harvard; Triumph mine near Ketchum; Idaho-Canadian Dredging Co. at Idaho City; Warren Dredging Co. at Warren; Boise King Placers near Twin Springs; De Lamar Milling Corporation at De Lamar; and Custer Consolidated Mines, Inc., near Sunbeam.

Silver.—The output of recoverable silver in Idaho was 16,672,410 fine ounces in 1941—a 5-percent decrease from 1940. Production from the Sunshine mine declined 1,045,470 ounces. The Coeur d'Alene region produced 88 percent of the State total silver in 1941; the rest came largely from the Warm Springs, Carson, Bayhorse, South Mountain, Middle Boise, Port Hill, and Pend d'Oreille districts. Silver ore yielded 59 percent of the State total silver, zinc-lead ore 30 percent, lead ore 6 percent, and gold-silver ore and gold ore 3 percent. The yield of silver from silver ore decreased 918,449 ounces and from zinc-lead ore 418,176 ounces, but that from zinc ore increased 193,405 ounces, from lead ore 176,184 ounces, and from gold ore and gold-silver ore 60,176 ounces.

Eight mines—the Sunshine, Bunker Hill & Sullivan, Mineral Point, Polaris, Hecla, Morning, Triumph, and Page—produced 84 percent of the silver output of the State in 1941. All these mines except the Triumph are in the Coeur d'Alene region.

Copper.—The output of recoverable copper in Idaho in 1941 was 7,242,000 pounds—an 8-percent increase over 1940. The gain resulted mainly from increased output of silver-copper ore from the Mineral Point mine. Silver ore (chiefly from mines in the Coeur d'Alene region) yielded 68 percent of the State total copper, zinc-lead ore 17 percent, copper ore 9 percent, and lead ore and zinc ore together 5 percent.

The Mineral Point and Sunshine mines produced 63 percent of the total copper output of the State in 1941.

Lead.—The output of recoverable lead in Idaho was 209,828,000 pounds in 1941—an increase of only 160,000 pounds over 1940. Marked increases at the Sherman, Tamarack, and Sunset mines prevented a decline, as a notable decrease took place at the Morning mine. About 91 percent of the State total lead came from the Coeur d'Alene region and 5 percent from the Warm Springs district; considerable lead was produced also in the Port Hill, Bayhorse, and Pend d'Oreille districts. Zinc-lead ore and old tailings from the Coeur d'Alene region and the Warm Springs district yielded 86 percent of the State total lead; and lead ore, chiefly from the Coeur d'Alene region, yielded 13 percent. Lead recovered from zinc-lead ore declined 4,482,205 pounds and from silver ore 710,597 pounds, but that from lead ore increased 4,971,053 pounds and from zinc ore 408,589 pounds.

In 1941 the combined lead output of the three largest producers—the Bunker Hill & Sullivan, Morning, and Hecla—was 127,137,585 pounds (138,817,322 pounds in 1940), or nearly 61 percent of the State total; other important producers were the Page, Star, Triumph, Tamarack, Sherman, Idaho-Continental, Gold Hunter, and Clayton properties.

Zinc.—The output of recoverable zinc in Idaho was 158,168,000 pounds in 1941– a 12-percent increase over the former record output (in 1940). The gain was due principally to increased output of zinc from mines in the Coeur d'Alene region and in the Warm Springs and South Mountain districts. Substantial increases in zinc output were made at the Star, South Mountain, Triumph, Tamarack, Sunset, and Highland Surprise properties. More than 86 percent of the State total zinc in 1941 came from the Coeur d'Alene region and nearly all the remainder from the Warm Springs and South Mountain districts. Zinc-lead ore and old tailings concentrated yielded 97 percent of the State total zinc, and zinc ore concentrated nearly all the remainder.

Seven mines—the Star, Morning, Bunker Hill & Sullivan, Triumph, Hecla, Tamarack, and Page—produced 85 percent of the State total zinc in 1941; the rest came chiefly from the South Mountain, Frisco, Sunset, Interstate-Callahan, and Highland Surprise properties.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Idaho in 1941, by counties, in terms of recovered metals

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline floating dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

[2] Recovered from 342,000 cubic yards of gravel treated by 12 dry-land dredges.

[3] Recovered from 2,000,000 cubic yards of gravel treated by 9 dragline floating dredges.

[4] Recovered from 10,612,000 cubic yards of gravel treated by 12 floating bucket dredges

MINING INDUSTRY

The marked increase in output of zinc, the gain in production of gold from dredging operations, and the reopening of several old zinc-lead producers in the Coeur d'Alene region were the most important features of the mining industry of Idaho in 1941. The production of

zinc was the largest in any year in the history of the State, and the output of placer gold was the largest since 1872, when 77,884 fine ounces were produced. Zinc-lead ore (by far the chief output of the State) increased 3 percent over 1940, silver ore nearly 7 percent, gold-silver ore 29 percent, copper ore 62 percent, lead ore 29 percent, and zinc ore from 101 to 22,551 tons; gold ore declined 7 percent.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Idaho in 1941, with content in terms of recovered metals

Source	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc
		Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*
Dry and siliceous gold ore	172	330, 354	62, 657	245, 418	33, 077	242, 165	------------
Dry and siliceous gold-silver ore	16	82, 465	5, 566	296, 475	6, 649	51, 954	------------
Dry and siliceous silver ore	31	490, 691	433	9, 869, 309	4, 951, 766	955, 543	------------
	[1] 217	903, 510	68, 656	10, 411, 202	4, 991, 492	1, 249, 662	------------
Copper ore	15	7, 979	696	43, 851	687, 128	21, 913	------------
Lead ore	57	212, 251	426	1, 043, 250	139, 760	27, 154, 356	3, 600
Lead-copper ore	3	174	2	22, 227	13, 006	70, 497	------------
Zinc ore	10	22, 551	378	193, 484	204, 300	408, 589	4, 965, 172
Zinc-lead ore	37	1, 558, 215	7, 263	4, 940, 988	1, 206, 314	180, 922, 983	153, 199, 228
Total, lode mines	[1] 331	2, 704, 680	77, 421	16, 655, 002	7, 242, 000	209, 828, 000	158, 168, 000
Total, placers	524	------	72, 395	17, 408	------------	------------	------------
	855	2, 704, 680	149, 816	16, 672, 410	7, 242, 000	209, 828, 000	158, 168, 000
Total, 1940	926	2, 556, 687	146, 480	17, 552, 240	6, 698, 000	209, 668, 000	141, 202, 000

[1] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

METALLURGIC INDUSTRY

Of the 2,704,680 tons of ore produced in 1941 in Idaho, 2,492,644 tons (92 percent) were treated at concentration plants, 179,503 tons (7 percent) were treated at amalgamation and cyanidation mills, and 32,533 tons (1 percent) were shipped crude to smelters.

Ore treated at concentration plants in 1941 comprised 145,840 tons of gold ore, 81,202 tons of gold-silver ore, 480,902 tons of silver ore, 3,906 tons of copper ore, 200,387 tons of lead ore, 22,313 tons of zinc ore, and 1,558,094 tons of zinc-lead ore.

Ore treated at straight amalgamation mills in 1941 totaled 15,673 tons yielding 3,057 ounces of gold and 2,797 ounces of silver. Ore treated at combined amalgamation and concentration plants comprised 157,648 tons yielding 17,817 ounces of gold and 10,086 ounces of silver in amalgamation bullion and 2,570 tons of concentrates containing 18,065 ounces of gold, 167,010 ounces of silver, and some copper and lead.

Ore (6,182 tons) treated at straight cyanidation plants in 1941 yielded 659 ounces of gold and 1,486 ounces of silver.

The lead smelter and refinery of the Bunker Hill & Sullivan Mining & Concentrating Co. at Bradley were operated continuously in 1941 on ore and concentrates, chiefly from the Bunker Hill & Sullivan,

Hecla, Star, Sunshine, Coeur d'Alene Mines Corporation, Polaris, Idaho-Continental, Gold Hunter, and Crescent mines, and zinc residue from the electrolytic zinc plant of the Sullivan Mining Co. The 100-ton electrolytic zinc plant of the Sullivan Mining Co. near Bradley operated at capacity, chiefly on zinc concentrates from the Star, Bunker Hill & Sullivan, and Hecla mills.

The Bunker Hill & Sullivan Mining & Concentrating Co. started building a fuming plant at Bradley in September to treat hot current slag and old slag containing principally zinc; this plant is expected to be operating in July 1942. The company also added to its milling plant a 1,700-ton H. & H. sink-and-float unit. The 400-ton gold mill at the Yellow Pine property at Stibnite was converted in August into a 200-ton mill to recover chiefly tungsten and antimony.

Mine production of metals in Idaho in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc

[1] Exclusive of antimony-tungsten-gold ore.

ADA COUNTY

Black Hornet district.—Adelmann Bros. operated their mine a short time in 1941 and treated a little gold ore by amalgamation.

Highland (Boise River) district.—Placer gold and silver were recovered by sluicing in 1941 at various claims along the Boise River 12 miles east of Boise.

Snake River district.—There was a marked increase in output of placer gold in the Snake River district of Ada County in 1941, owing to operation of three dry-land dredges near Grand View; the largest production came from ground worked by Cecil Rhodes.

ADAMS COUNTY

Seven Devils district.—Lessees operated the Placer Basin mine near Cuprum in 1941 and shipped several cars of gold ore to a smelter; nearly all the remainder of the district output was copper ore from the Helena and South Peacock properties.

Snake River district.—Placer gold was recovered in 1941 by sluicing at various claims along the Snake River near Homestead.

BLAINE COUNTY

Mineral Hill and Camas district.—The output of the Mineral Hill and Camas district in 1941 was largely old tailings (gold) treated by cyanidation from the Daisy property, old tailings (silver) shipped from the Minnie Moore property, and gold ore and old tailings from the Camas property.

Sawtooth (Vienna) district.—About 35 tons of gold-silver ore was shipped from the Vienna mine in 1941 and a little silver ore from the Silver King mine.

Warm Springs district.—Except for the Coeur d'Alene region, the Warm Springs district near Ketchum continued to be the most important producing area in Idaho; the value ($2,667,080) of its metal output increased 14 percent in 1941 over 1940. Zinc-lead-silver ore (about 97,000 tons) from the Triumph-North Star-Independence groups was again the chief output of the district; the rest of the district output was principally gold ore and old tailings from the June Day property and gold-silver ore and lead ore from Boulder Basin Mines.

BOISE COUNTY

Banner district.—The only output of the Banner district in 1941 was old mill cleanings sold to an assayer in Boise and placer gold recovered from the Gold Fork claim.

Boise Basin district (Centerville, Placerville, Idaho City, Pioneerville, Quartzburg).—The production of ore and of each metal, especially gold and silver, in the Boise Basin district was less in 1941 than in 1940. The most important output was, as usual, placer gold from dredging operations, but gold from this source decreased 13 percent from 1940. The Fisher-Baumhoff Co., operating two bucket dredges at Centerville, was again the largest producer of placer gold in the State; the two dredges handled 2,529,000 cubic yards of gravel and recovered 12,007 fine ounces of gold. The Idaho-Canadian Dredging Co. operated its 7½-cubic foot bucket dredge at Idaho City throughout the

year and recovered more than 5,500 fine ounces of gold. Considerable gold was also recovered by two dragline floating dredges—one operated by M. A. Stickler on Moores Creek and the other by Smith Bros. on Grimes Creek—and by hydraulicking and sluicing at Gold Hill Placers at Idaho City. The most important lode operation in the district during 1941 was that of the Come-Back Mining Co.; this company operated its mine at Pioneerville continuously and shipped 192 tons of high-grade gold-silver ore to a smelter.

Eight Mile Creek district.—Birthday Consolidated Gold Mines, Inc., operated its mine near Lowman throughout 1941; about 2,400 tons of gold ore were treated in a 25-ton concentration plant, and 174 tons of crude ore were shipped to a smelter.

Grimes Pass district.—The output of the Grimes Pass district in 1941 was principally gold ore and zinc-lead ore from the Homestake-Coon Dog group, gold ore and lead ore from the Santa Clara mine, and placer gold chiefly from the J. S., Horseshoe, and Golden Age properties.

Miller Creek district.—Placer gold and silver were recovered in 1941 by sluicing at the Miller Mountain claim.

North Fork district.—In 1941 about 15 tons of silver ore were shipped from the Packer John claim near Smiths Ferry.

Rabbit Creek district.—Hydraulicking and sluicing at the Rabbit Creek Placer recovered a little gold and silver.

Shaw Mountain district.—The Little Dave mine was operated in 1941, and gold ore was treated by amalgamation.

South Fork of Payette River district.—Placer gold was recovered in 1941 by sluicing at various claims along the South Fork of the Payette River near Lowman.

Summit Flat district.—Virtually all the output in the Summit Flat district in 1941 was gold ore treated by amalgamation; 82 percent of the output came from the King mine.

BONNER COUNTY

Lakeview district.—The Hewer (Idaho Lakeview) mine was the only producer in the Lakeview district in 1941; several hundred tons of silver ore were treated in a 75-ton flotation plant.

Pend d'Oreille district.—In 1941, as in 1940, nearly all the output of the Pend d'Oreille district was silver-lead ore, treated by flotation, from the Hope (Elsie K.) and Whitedelf mines; however, the output from the Hope property was much less than in 1940. The Whitedelf mine was by far the most important producer in the district.

BONNEVILLE COUNTY

Virtually all the output of Bonneville County in 1941 was placer gold recovered by hydraulicking and sluicing, largely from the Rosana, Lottie, and McCoy Creek properties in the Mt. Pisgah district.

BOUNDARY COUNTY

In 1941, as in 1940, the only producer in Boundary County was the Idaho-Continental mine in the Port Hill district; 37,000 tons of silver-lead ore were treated by flotation.

BUTTE COUNTY

Dome district.—The output of the Dome district in 1941 was 2,500 tons of lead ore, treated by gravity concentration, from the mine dump at the Wilbert property.

Hamilton district.—Small lots of rich copper ore were produced in 1941 from the Copper Mountain prospect.

Lava Creek district.—Silver ore was produced in 1941 from the Hornsilver mine, silver-lead ore from the Lead Belt mine, gold-silver ore from the Moran mine, and zinc ore from the Multa Metals group.

CAMAS COUNTY

Beaver Creek (Mineral Hill) district.—Lessees operated the Princess-Blue Ribbon mine in 1941 and shipped 988 tons of gold ore and 44 tons of lead ore to smelters in Utah; the output was much less than in 1940.

Little Smoky and Carrietown district.—The output of the Little Smoky and Carrietown district in 1941 was chiefly silver ore and old tailings from the King of the West property, silver ore from the Horn Silver mine, and gold-silver-copper ore from the Grant mine.

Skeleton Creek district.—Lessees operated the El Oro mine in 1941 and treated about 600 tons of gold ore by gravity concentration. The remainder of the district output was principally high-grade gold ore from the Red Horse claim.

CASSIA COUNTY

Virtually all the output of Cassia County in 1941 was silver ore from the Silver Hills claim in the Blackpine district and gold-lead ore from the Big Bertha mine in the Stokes district.

CLEARWATER COUNTY

Burnt Creek district.—The output of the Burnt Creek district in 1941 was placer gold and silver; the chief producer was the Frank Bish claim near Elk River.

Moose Creek and Independence Creek district.—The output of placer gold in the Moose Creek and Independence Creek district increased in 1941, owing to operation, from June to October, of a dry-land dredge at the Alma claim by Placer Properties of Idaho, Inc.

Pierce district.—Production of placer gold in the Pierce district decreased nearly 45 percent in 1941 compared with 1940, owing to suspension of dredging by the Quartz Creek Dredging Co. in March. A greater decrease was prevented by the operation of two dragline floating dredges—one at the Crawford Placer by the J. M. S. Co. and the other at the French Creek Placers by the Pilot Dredging Co. Nearly all the gold output from lode mines in the district was produced from the Gold Quartz claim.

CUSTER COUNTY

Alder Creek district.—The principal output in the Alder Creek district in 1941 was copper ore, containing gold and silver, from the Empire mine at Mackay; however, the output declined from 4,500 tons in 1940 to 3,169 tons in 1941. The rest of the district output was largely lead ore from the Horseshoe mine and zinc ore and lead ore from the White Knob property.

Bayhorse district.—The value of the metal output of the Bayhorse

district was 35 percent greater in 1941 than in 1940, chiefly in consequence of the increase in output of silver and lead from the Clayton property. This mine was operated continuously, and 36,880 tons of silver-lead ore were treated by flotation. In November the company (Clayton Silver Mines) began to erect an addition to its mill building to house a zinc-recovery plant. Lessees continued to operate the Ramshorn mine and shipped 938 tons of lead-silver ore and lead-copper-silver ore. The rest of the district output was largely silver-lead ore from the Riverview and South Butte properties.

Boulder district.—Lessees continued to operate the Livingston mine and treated 114 tons of silver-lead ore by gravity concentration.

East Fork district.—A small lot of lead ore was produced in 1941 from the F. D. R. prospect.

Loon Creek district.—A little high-grade gold ore was produced in 1941 from the Last Chance claim and placer gold from the Brush claim.

Seafoam district.—There were four producers in the Seafoam district in 1941, but most of the output was crude gold ore from the Lake View mine.

Stanley and Stanley Basin district.—The decline in metal output in the Stanley and Stanley Basin district in 1941 resulted from suspension in April of production of crude gold-silver ore from property operated by the Western Gold Exploration Co. The company worked most of the year on development and in building a new 100-ton concentration and cyanidation plant. Placer gold and silver were recovered, largely from the Elk Creek Placer, by a dragline floating dredge.

Yankee Fork district.—The value of metal production in the Yankee Fork district in 1941 was $463,910—an increase of $294,912 over 1940. The principal output was placer gold from the Yankee Fork Placer and lode gold and silver from the General Custer-Lucky Boy group. The marked increase in placer gold resulted from regular operation of the 8-cubic foot bucket dredge of the Snake River Mining Co. at the Yankee Fork property. About 16,000 tons of gold ore from the General Custer-Lucky Boy group were treated by amalgamation and concentration.

ELMORE COUNTY

Bear Creek district.—Gold ore was produced in 1941, chiefly from the Avalanche-Richmond, Luck, Duces Wild, and Jungo properties.

Boise River (Twin Springs) district.—Small-scale placer operators along the Boise River near Twin Springs recovered 43 fine ounces of gold and 14 fine ounces of silver in 1941.

Middle Boise (Atlanta) district.—The value of the metal output of the Middle Boise district increased to $1,056,289 in 1941, owing to substantial gain in output of gold from the Boise-Rochester-Monarch groups and to operation of a new 7½-cubic foot bucket dredge by Boise King Placers. Talache Mines, Inc., operated its property (Boise-Rochester-Monarch) continuously and treated 121,355 tons of gold ore by amalgamation and concentration; this property, with a production of 23,027 fine ounces of gold in 1941, remained the chief producer of gold in Idaho. Boise King Placers became a large producer of placer gold through operation, from June 15 to December 31, of a bucket-line dredge.

Snake River district.—Placer gold was recovered in 1941 by various operators along the Snake River near King Hill.

GEM COUNTY

West View district.—The principal output of the West View district in 1941 was lode gold and silver from the Lincoln group and placer gold from the Cruickshank property. Huron Mines, Inc., operated the Lincoln group and treated 11,274 tons of gold ore by flotation. A dragline floating dredge at the Cruickshank property recovered about 600 fine ounces of gold and 66 fine ounces of silver; the equipment was moved in June to a property near Idaho City, Boise County.

IDAHO COUNTY

Burgdorf-Marshall Lake district.—Gold ore from the Golden Anchor mine was again the chief output of the Burgdorf-Marshall Lake district, but the output declined from 15,459 tons in 1940 to 13,367 tons in 1941. Other producers of gold ore included the Gold Crest, Jewel, Kimberly, Old Kentuck, and Warrior properties. Nearly all the output of placer gold and silver was recovered by hydraulicking and sluicing at the Ruby placers and the Black Creek and Golden Rule properties.

Camp Howard (Salmon River) district (White Bird).—Hydraulicking and sluicing and drift mining at various claims along the Salmon River near White Bird recovered 116 fine ounces of gold and 24 fine ounces of silver in 1941.

Dixie district.—The principal output of the Dixie district in 1941 was placer gold recovered by a dragline floating dredge at Dixie Placers and lode gold, mostly from the Slip Easy, Dixie Royal, Ontario, and North Star properties.

Elk City district.—In 1941 six dredges in the Elk City district treated 1,796,883 cubic yards of gravel and recovered 13,387 fine ounces of gold and 2,525 fine ounces of silver, nearly double the output in 1940; the bucket-line dredge on Crooked River, operated by H. & H. Mines, was by far the largest producer. Other large producers were the American River Mining Co., Tyee Mining Co., and Lloyd Barker. Nearly all the lode gold produced in the district in 1941 came from gold ore and old tailings amalgamated at the Blue Ribbon property, operated by the Elk Leasing Corporation.

Florence and French Creek district.—Numerous small lots of placer gold and silver were recovered by operators in the Florence and French Creek district in 1941, and a little lode gold and silver was produced from the Golden Dyke and Sines claims.

Lolo Creek district.—Thirteen fine ounces of placer gold were recovered in 1941 from gravel along Lolo Creek.

Lower Salmon River district.—The output of the Lower Salmon River district in 1941 was placer gold and silver, recovered chiefly from the Swiftwater and Sunshine properties.

Newsome district.—Gold output in the Newsome district was much greater in 1941 than in 1940, owing to the operation of a dragline floating dredge at property on Newsome Creek by Gold Hill Placers.

Orogrande district.—The Mt. Vernon Co. operated its 2-cubic foot bucket dredge at property on Crooked River 9 months of the year and recovered about 2,000 fine ounces of gold and 430 fine ounces of silver. Nearly all the remainder of the district output was gold and silver produced from the Penman lode mine.

Ramey Ridge district.—Snowshoe Gold, Inc., operated the Snowshoe

mine in 1941; about 2,500 tons of gold ore were treated by amalgamation and concentration. The rest of the district output was small lots of gold ore from the Estep, Hand, and Werdenhoff properties.

Robbins (Buffalo Hump) district.—The output of the Robbins district in 1941 was gold ore, principally from the Jumbo, St. Louis, and Mother Lode properties.

Salmon River (Shoup) district.—Small-scale placer operators recovered 42 fine ounces of gold and 7 fine ounces of silver in 1941 at various bars along the Salmon River in Idaho County below Shoup.

Simpson (Salmon River) district (Lucile).—The principal producers of placer gold in the Simpson district in 1941 were the Wild Cat, Betty Jean, Katie B., and J. K. T. properties.

Snake River district.—Sluicing at various claims on the Snake River below Lewiston recovered 54 fine ounces of gold and 7 fine ounces of silver in 1941.

Ten Mile district (Golden).—Lessees operated the Center Star mine throughout 1941 and treated about 6,800 tons of gold ore by concentration; this mine was by far the most important producer in the district. Other producers of gold ore included the Bob, Lone Pine, Shamrock, and Wonder properties. Placer gold and silver were recovered by hydraulicking and sluicing at Key Placers.

Warren district.—Gold output in the Warren district declined to 6,690 fine ounces in 1941, owing to decreased output of gold from bucket dredging. The Warren Dredging Co., largest producer in the district, operated two bucket dredges from January 1 to August 10, when it sold its placer ground and one dredge to W. W. Prather, who operated the property the remainder of the year. Production of gold from lode mines in the district came mainly from the Rescue property.

JEROME COUNTY

Production from Jerome County in 1941 was, as usual, placer gold and silver recovered by various operators along the banks of the Snake River near Murtaugh, Hansen, Eden, and Twin Falls.

LATAH COUNTY

Hoodoo district.—The output of the Hoodoo district in 1941 was placer gold and silver, virtually all recovered by the 4½-cubic foot bucket-line dredge of Northwest Goldfields.

Moscow Mountain district.—The output of 17 fine ounces of placer gold in the Moscow Mountain district in 1941 was recovered chiefly from Leith Placer.

LEMHI COUNTY

Blackbird district.—The Uncle Sam mine was the only producer in the Blackbird district in 1941; 3,256 tons of copper ore were treated by flotation, and 21 tons of copper ore were shipped crude to a smelter.

Blue Wing district.—About 29,000 tons of ore from the Ima mine containing galena, pyrite, and certain strategic minerals were treated in 1941. Iron concentrates containing gold, silver, copper, and lead were shipped to a smelter in Utah.

Eldorado district.—A small lot of copper ore was produced in 1941 from the Mountainview claim, and some old mill cleanings (gold) from the Ranger mill were sold to an assayer.

Eureka district.—The principal output in the Eureka district in 1941 was gold ore (amalgamated) from the Queen of the Hills mine and copper ore (concentrated) from the Pope-Shenon and Grand View properties.

Gibbonsville district.—Output of placer gold in the Gibbonsville district showed a marked increase in 1941, owing to the operations of two dredges. A dragline floating dredge was operated by Smith Bros. at the Hagle property, and a 4½-cubic foot bucket-line dredge was operated the last quarter of the year at Hughes Creek Placer by the Idaho-Warren Dredging Co.; Smith Bros. was by far the larger producer. Hydraulicking and sluicing at the Sundown property recovered considerable placer gold. Most of the gold output from lode mines in the district came from the Nevada, McCarthy, and Providencia properties.

Indian Creek district.—The output of the Indian Creek district in 1941 was gold ore (concentrated) from the Kittie Burton & Ulysses group.

Junction district.—A little lead ore was produced in 1941 from the Dirigo and Plymouth properties near Leadore.

Kirtley Creek district.—In 1941, 45 fine ounces of gold and 7 fine ounces of silver were recovered by drift mining by various placer operators on Kirtley Creek.

Mackinaw district.—The principal output of the Mackinaw district in 1941 was placer gold from the Richardson property at Leesburg, where a 1¾-cubic yard dry-land dredge recovered more than 1,000 fine ounces of gold and 115 fine ounces of silver.

Mineral Hill district.—Gold Producers, Inc., operated the Grunter mine at Shoup throughout the year and treated 27,689 tons of gold ore by flotation. The rest of the district output was mainly gold ore from the Gold Hill and Meadow Mountain properties.

Parker Mountain district.—Small lots of rich gold ore were produced in 1941 from the Pinch Hit claim.

Salmon River district.—The Salmon River Dredging Co. operated its floating washer, equipped with a suction nozzle, a few months in 1941 and recovered about 50 fine ounces of gold and 8 fine ounces of silver. Other placer producers included the Bean Bar and Homestake properties.

Spring Mountain district.—A little silver-lead ore was produced in 1941 from the Galena and Red Warrior claims and copper ore from the Mountain Bell prospect.

Texas district.—The output of the Texas district in 1941 comprised 2,600 tons of gold ore (treated by cyanidation) from the Allie (Falls Creek) mine and 939 tons of crude silver-lead ore from the Latest Out property.

Yellow Jacket district.—Lessees operated the Yellow Jacket mine near Forney in 1941 and treated about 700 tons of gold ore by flotation and shipped 21 tons of rich gold ore to a smelter. The remainder of the district output was chiefly gold ore from the Bryan mine.

LEWIS COUNTY

Placer gold and silver were recovered in 1941 from gravel along the Clearwater River near Greer and Kamiah and from the Salmon River south of Forest.

NEZ PERCE COUNTY

The metal output of Nez Perce County in 1941 was principally placer gold recovered from gravel by various operators working along the Clearwater River near Myrtle and the Snake River below Lewiston.

OWYHEE COUNTY

Carson district (Silver City, De Lamar).—The principal production in the Carson district in 1941, as in 1940, was gold and silver recovered from the milling of old tailings (81,202 tons in 1941) by the De Lamar Milling Corporation. The rest of the district lode output was largely silver ore from the Henrietta and Trade Dollar mines, gold ore from the Poorman-Pauper group, and gold-silver ore from the South Central mine. Most of the placer gold and silver came from the Lewis property and from cleanings from an old dredge.

Castle Creek district.—Small lots of gold-silver ore were produced in 1941 from the Badger and Elliott claims and a little gold ore from the Buck Horn prospect.

Snake River district.—The output of placer gold in the Snake River district near Grand View was much less in 1941 than in 1940, owing to the decreased output from dredging operations. Two dry-land dredges—one operated by Cecil Rhodes and the other by F. R. Knowlton—recovered about 600 fine ounces of gold and 31 fine ounces of silver in 1941.

South Mountain district.—Continuous operation of the Golconda mine by the South Mountain Mining Co. in 1941 resulted in a marked increase in metal output from the South Mountain district; 16,663 tons of zinc ore containing gold, silver, lead, and copper were shipped to the custom flotation mill at Tooele, Utah, and 423 tons of silver-copper ore were shipped to a smelter.

Steele district.—The only output in the Steele district in 1941 was 23 tons of gold ore from the Morning Glory mine.

POWER COUNTY

The metal output of Power County in 1941 was placer gold recovered by sluicing at the Bonanza Queen and Eagle Rock properties on the Snake River near American Falls.

SHOSHONE COUNTY

COEUR D'ALENE REGION

The value of the metal output of the Coeur d'Alene region increased 10 percent in 1941 over 1940, owing chiefly to the gain in output of zinc; the output of copper also increased, but the output of gold, silver, and lead decreased. Copper increased 11 percent and zinc 9 percent; and gold decreased 50 percent, silver 6 percent, and lead less than one-half of 1 percent. The output of zinc was the largest in the history of the region and resulted chiefly from marked increases at the Star, Tamarack, Sunset, and Highland Surprise properties. More than 71 percent of the material produced in Shoshone County in 1941 was zinc-lead ore and old tailings, 22 percent silver ore, and 6 percent lead ore.

Of the total metal output in Idaho in 1941, the Coeur d'Alene region produced 88 percent of the silver, 82 percent of the copper, 91 percent of the lead, and 86 percent of the zinc.

The following table gives the production of gold, silver, copper, lead, and zinc in the Coeur d'Alene region in 1940 and 1941 and the total for 1884 to 1941.

Mine production of gold, silver, copper, lead, and zinc in the Coeur d'Alene region, Shoshone County, 1940–41, and total 1884–1941, in terms of recovered metals

Year	Mines producing		Ore	Gold (lode and placer)	Silver (lode and placer)	Copper	Lead	Zinc	Total value
	Lode	Placer							
			Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*	
1940	49	25	1,917,235	6,886	15,616,852	5,359,000	191,218,460	125,896,000	$29,444,265
1941	58	21	2,051,390	3,419	14,678,356	5,957,000	191,057,000	136,642,000	32,398,932
Total, 1884–1941			(1)	382,397	387,566,608	[2] 57,267	[2] 5,138,989	[2] 808,233	939,211,323

[1] Figures not available. [2] Short tons.

Beaver district.—The value of metal production in the Beaver district was $879,982 in 1941, or more than double that in 1940. Substantial increases were recorded in output of silver, copper, lead, and zinc, but the output of gold decreased. The most important producer was the Sunset mine, operated under lease; 25,416 tons of zinc-lead ore were milled in the Golconda custom flotation plant in 1941 compared with 5,603 tons in 1940; and the mine was the largest producer of silver, copper, lead, and zinc in the district. The Interstate Lease continued to operate the Interstate-Callahan property, and 16,000 tons of zinc-lead ore were treated in the Galena mill. This 200-ton mill, owned by the Callahan Zinc-Lead Co., was purchased in 1941 by Zanetti Bros., who operated the plant on custom ores and old tailings; 30,000 tons of old zinc-lead tailings were treated from the Interstate-Callahan dump, under lease to Zanetti Bros. The rest of the district lode output was mostly zinc-lead ore from the Silver Tip (Portland) and Monarch properties. The output of placer gold in the district was much less than in 1940, owing to suspension early in 1941 of dredging by the Beaver Dredging Co. Other placer producers included the Accident and Lock & Erwin claims.

Coeur d'Alene district.—About 72 tons of gold ore were produced in 1941 from the Mountain Lion mine; placer gold and silver were recovered from the Beehive Bar, Joe Gandy, and Otis properties.

Eagle district.—A lessee operating the Crystal Lead property in 1941 hauled 300 tons of lead ore to the Silver Crescent custom mill near Osburn and shipped 20 tons of similar ore to a smelter. A little placer gold was recovered from two claims on Eagle Creek.

Evolution district.—Production of silver in the Evolution district continued to decline in 1941, owing to the decrease in silver content of the Sunshine ore; the output of silver ore from the mine increased from 278,810 tons in 1940 to 305,180 tons in 1941, and the mine is still the largest producer of silver in the United States. The drop in gold output of the district resulted mainly from suspension of dredging at placer properties near Murray; and the gain in output of copper resulted from the increase in silver-copper ore from the Mineral

Point mine. The Sunshine Mining Co. reported that 7,748 tons of concentrates contained 7,138,426 ounces of silver, 2,394,641 pounds of copper, 258,855 pounds of lead, and some antimony. The milling ore treated at the Sunshine mill in 1941 contained an average of 241 ounces of silver to the ton, 0.4 percent copper, a trace of lead, and some antimony. A new plant is under construction to treat the entire production of silver-copper-antimony concentrates. Output of silver-copper ore from the Mineral Point mine of the Coeur d'Alene Mines Corporation increased from 51,209 tons in 1940 to 87,672 tons in 1941; the daily capacity of the 300-ton flotation mill was increased to 600 tons. The company reported that the concentrates contained 1,447,267 ounces of silver, 2,768,284 pounds of copper, and some antimony. The property was the largest producer of copper in Idaho and ranked third in silver output. The Polaris Mining Co. operated its mine and 200-ton mill continuously and treated 47,554 tons of silver ore, a slight decrease from 1940. The rest of the district output was principally old zinc-lead tailings from a dump near Wallace.

Hunter district (Mullan).—The output of ore and the quantity of each metal produced in the Hunter district were less in 1941 than in 1940, but the total value of the output was greater, owing to the increase in average sales price of copper, lead, and zinc. The output of recoverable zinc (64,455,400 pounds) was larger than in any district in Idaho, and the output of recoverable lead was exceeded by only one district (Yreka). Zinc-lead-silver ore from the Morning mine of the Federal Mining & Smelting Co. continued to be the chief output, but it declined from 336,603 to 270,787 tons. The average grade of the ore mined during 1941 was 3.1 ounces of silver to the ton, 7.3 percent lead, and 7.2 percent zinc. Ore reserves at the end of 1941, including developed and probable ore, are estimated at 687,000 tons. The company reported that the concentrates produced contained 207 ounces of gold, 787,009 ounces of silver, 37,232,772 pounds of lead, and 34,817,432 pounds of zinc. The property ranked second in the State in lead and zinc output and sixth in silver. The Sullivan Mining Co. operated its Star mine and 1,000-ton flotation plant throughout the year; 212,420 tons of zinc-lead ore were treated in 1941 compared with 214,464 tons in 1940. The company reported that the concentrates produced contained 209,808 ounces of silver, 14,037,830 pounds of lead, and 37,127,957 pounds of zinc. The mine was the largest producer of zinc in Idaho in 1941. Lessees continued to operate the Gold Hunter mine, and 49,942 tons of silver-lead ore were treated in the 500-ton Gold Hunter flotation plant. The rest of the district output was mainly zinc-lead ore from the Golconda mine.

Lelande district (Burke, Mace, Frisco).—The value of the metal production of the Lelande district was $4,777,186 in 1941—a gain of 14 percent over 1940; the output of each metal except zinc increased. The Hecla mine remained the most important producer in the district; 204,662 tons of zinc-lead-silver ore were treated in the company 900-ton flotation mill, and 7,282 tons of crude silver-lead ore were smelted. The company reported that the concentrates and crude ore contained 945,240 ounces of silver, 30,083,418 pounds of lead, and 17,255,660 pounds of zinc. The Sherman Lead Co. was a large producer of silver-lead ore in 1941; 52,066 tons of ore were treated in

the company 300-ton flotation plant—a marked increase over 1940. The ore treated in 1941 averaged 6.4 ounces of silver to the ton and 10.8 percent lead. The Hull Leasing Co. continued to work the Frisco mine and treated 32,000 tons of zinc-lead ore in its 100-ton flotation mill. The remainder of the district output was mostly zinc-lead ore from the Black Bear mine.

Placer Center district.—The marked increase in output of silver, lead, and zinc in the Placer Center district in 1941 resulted chiefly from the greater output of zinc-lead ore from the Tamarack mine—by far the most important producer in the district. The mine and 300-ton mill were operated continuously by the Tamarack & Custer Consolidated Mining Co.; 97,008 tons of zinc-lead ore were treated by flotation, compared with 56,121 tons in 1940. According to the printed annual report of the company, the mine is prepared for maximum production in 1942. A greater tonnage of ore is in sight now than there was in 1940; however, the grade of the ore will be lower in metal content in 1942 than in 1941, when it averaged 1.9 ounces of silver to the ton, 5.5 percent lead, and 7.3 percent zinc. A new 200-ton mill was built at the Dayrock property in 1941, and during the last quarter of the year 4,651 tons of silver-lead ore were treated by flotation; in addition, 6,630 tons of similar ore were treated in the Hercules custom mill. The ore milled averaged 7.7 ounces of silver to the ton and 8.7 percent lead. The rest of the district output was principally old zinc-lead tailings (12,665 tons) from various dumps near Wallace and zinc-lead ore from the Success mine.

St. Joe district.—Small lots of placer gold were recovered in 1941 from the Gold Producers, Grizzly, and Iron Hill claims, and a little copper ore was produced from the Hansy and Monitor properties.

Summit district (Murray).—Output of gold in the Summit district decreased sharply in 1941, owing to suspension in April of operations at the Golden Chest mine; before the mine closed, about 3,000 tons of gold ore had been concentrated. Zinc-lead ore (91 tons) was produced from the Anchor mine. Placer gold and silver were recovered by various operators working on Coeur d'Alene Mining Co. ground.

Yreka district (Kellogg).—The value ($8,711,318) of the metal output of the Yreka district in 1941 was the largest in any district of Idaho, but it exceeded that of the Hunter district by only $6,677. The production of recoverable lead was greater than in any district of the State, and that of recoverable zinc and silver ranked second. Zinc-lead ore from the Bunker Hill & Sullivan mine was again the chief output in the district; 385,060 tons were treated in the company 1,200-ton flotation plant, compared with 383,886 tons in 1940. A new 1,700-ton sink-and-float unit, added to the mill during the year, was put in operation December 1. The property remained the largest producer of lead in Idaho, second in output of silver, and third in zinc. The company reports that ore reserves on January 1, 1942, fully developed and ready to mine, totaled 2,730,398 tons of zinc-lead-silver ore. The Federal Mining & Smelting Co. operated the Blackhawk and Page mines and the Page 500-ton mill throughout the year; 102,352 tons of zinc-lead ore from the Page mine and 11,854 tons of similar ore from the Blackhawk were treated. The Highland Surprise property was reopened early in the year, after being idle since April 1927, and 21,000 tons of zinc-lead ore were treated in the company 100-ton flotation mill. The old Constitution (Spokane-Idaho) mine

also was reopened, and 6,973 tons of zinc-lead ore were treated by flotation. About 10,000 tons of silver ore from the Crescent group were concentrated, and 1,536 tons of similar ore were shipped to a smelter. The rest of the district output was largely zinc-lead ore from the Little Pittsburg, Liberal King, and Nabob properties.

TWIN FALLS COUNTY

The metal output of Twin Falls County in 1941 was, as usual, placer gold and silver recovered by sluicing at various properties along the Snake River.

VALLEY COUNTY

Big Creek district.—Nearly all the output of the Big Creek district in 1941 was gold ore concentrated from the Sunday mine.

Deadwood Basin district.—A little placer gold recovered from claims on Bummer Creek and Deadwood Creek was the only output in the Deadwood Basin district in 1941.

Lake City (McCall) district.—Hydraulicking and sluicing in 1941 at the Neely Hill and Boulder Creek properties recovered a little placer gold and silver.

Pistol Creek district.—Gold-lead ore from the Lucky Boy mine continued to be the only output in the Pistol Creek district.

Thunder Mountain district.—A substantial increase was made in output of gold in the Thunder Mountain district in 1941, owing to operation of the Sunnyside mine and mill by the Gold Reef Mining Co.; 9,300 tons of gold ore were treated by amalgamation. Placer gold and silver were recovered chiefly from the Dewey claim.

Yellow Pine district.—The Bradley Mining Co. operated the Yellow Pine property throughout 1941. However, the output of antimony-gold ore declined from 132,297 tons in 1940 to 80,658 tons in 1941, resulting in a substantial decrease in gold output for district. In August the 400-ton gold mill was converted into a 200-ton mill.

WASHINGTON COUNTY

Nearly all the output in Washington County in 1941 was silver-copper ore from the Silver Still mine and gold-copper ore from the Condor property, both in the Washington (Mineral Creek) district.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN MONTANA

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

SUMMARY

The Montana output of gold, silver, copper, lead, and zinc had a greater aggregate value in 1941 than in 1940, but only the quantity of copper, silver, and zinc increased. The total value of the five metals was $59,181,627 compared with $55,825,078 in 1940 (see fig. 1). The gold output from several of the larger lode gold mines throughout the State dropped sharply; the output from placer mines was slightly less than in 1940. The decline in lead output in 1941 was due in part to a general decline in production at several large lead-producing mines and in part to suspension of operations at the Comet mine in Jefferson County after 3 months of operation. The value of the metal output from Silver Bow County—by far the most productive area in the State and from which virtually all the copper and much of the zinc and silver are derived—was $44,195,725 in 1941 compared with $40,871,719 in 1940. This increase was due to near-capacity operations of the Anaconda Copper Mining Co.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35 00	$0 7735	$0 121	$0 059	$0.065
1938	35 00	[4] 646+	.098	046	.048
1939	35 00	[5] 678+	.104	.047	.052
1940	35 00	[6] 711+	.113	050	.063
1941	35 00	[6] .711+	.118	057	075

[1] Price under authority of Gold Reserve Act of January 31, 1934 Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20 67+ ($20 671835) per fine ounce

[2] 1937: Yearly average weighted Treasury buying price for newly mined silver, 1938–41. Treasury buying price for newly mined silver

[3] Yearly average weighted price of all grades of primary metal sold by producers.

[4] $0.64646464. [5] $0 67878787. [6] $0 71111111.

Mine production of gold, silver, copper, lead, and zinc in Montana, 1937–41, and total, 1862–1941, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1937	615	406	4,898,009	202,252	$7,078,820	11,812,093	$9,136,654

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."
[2] Figures for sluicing and hydraulic include those for drift mining.

Gold.—Montana ores and gravels yielded 246,475 fine ounces of gold in 1941 compared with 272,602 ounces in 1940—a 10-percent decrease. In 1941 the output from lode mines decreased 23,591 ounces and that from placer mines 2,536 ounces. Siliceous ores yielded 64 percent of the State total and base metal-ores 11 percent; there was a decrease from siliceous ores but an increase from copper, lead, and zinc-lead ores. Gains were noted in output of recovered gold from Park, Silver Bow, Broadwater, Ravalli, and Cascade Counties but losses from Lewis and Clark, Madison, Jefferson, Powell, and Phillips Counties Gold ore mined in 1941 totaled 695,481 tons compared with 803,173 tons in 1940 and included 542,870 tons treated in amalgamation and cyanidation mills, 99,293 tons in concentrating mills, and 53,318 tons shipped crude to smelters. Ore treated at

amalgamation and cyanidation plants (with or without concentrating equipment) yielded 29 percent of the State total gold, that at concentrating mills 22 percent, ores of all classes shipped crude to smelters 24 percent, and placers 25 percent.

The leading gold producer in Montana was again the West Mayflower property in Madison County, operated by the Anaconda Copper Mining Co.; it was followed by all company-operated copper mines at Butte, the Ohio Keating mine in Broadwater County, the

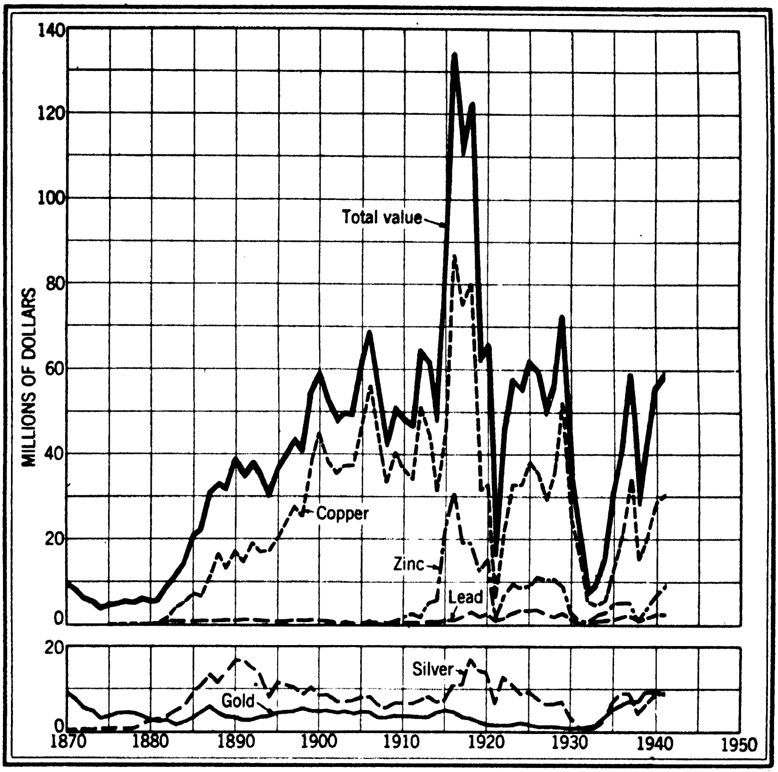

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc and total value in Montana, 1870–1941.

Winston dredge operating on Prickly Pear Creek near Clancey, the Ruby Gulch mine at Zortman, and Porter Bros. dredge near Helena.

Silver.—The output of recoverable silver in Montana in 1941 was 12,386,925 fine ounces, virtually the same as in 1940. Copper ore yielded 50 percent of the State total silver, zinc-lead ore 24 percent, and siliceous ore 24 percent. Ore treated at concentration mills yielded 82 percent of the total silver and crude smelting ore 17 percent. The output of silver ore was 122,684 tons and of gold-silver ore 121,902 tons.

The copper mines, dumps, and zinc mines at Butte and the Flathead mine in Flathead County, all operated by the Anaconda Copper Mining Co., produced 73 percent of the State silver. Other large producers included the Lexington group in the Montana district,

Cascade County; the Granite-Bimetallic mine (tailings) in Granite County; the Emma mine at Butte (including byproduct silver); and the Florence mine in Cascade County.

Copper.—Copper produced in Montana in 1941, in terms of recoverable metal, showed a gain of 3,290,000 pounds in quantity and $1,652,130 in value over 1940. Copper ore and precipitates yielded recoverable gold, silver, copper, and lead valued at $34,296,577 or 58 percent of the value of the State output. The Anaconda Copper Mining Co. was, as usual, the only important copper producer in Montana; although the output of copper from all sources of company operations in the Butte district showed a net gain, the output of copper from company mines, precipitates, and old mine dumps showed a decrease from 1940 which was more than offset by the copper recovered from the milling of old works tailings. In 1941 the company shipped 2,869,051 tons of copper ore to the mills compared with 2,737,572 tons in 1940, 405,862 tons of mine-dump material compared with 510,972 tons in 1940, and 512,930 tons of old tailings compared with none in 1940. In addition, 36,596 tons of crude ore and 32,881 tons of old tailings were shipped direct to the smelter.

Lead and zinc.—The value of the output of lead and zinc in Montana, in terms of recoverable metals, showed increases in 1941 over 1940; however, the increase in total value of the lead was due to the higher average price for the metal, inasmuch as the quantity decreased. Zinc showed a 37-percent increase in value and a 15-percent gain in quantity; lead a 5-percent increase in value but an 8-percent decrease in quantity. All zinc mines, plus the Anaconda slag-fuming plant at East Helena, showed a gain over 1940 of 14,091,956 pounds in recovered zinc but a loss of 104,154 pounds in lead. The Emma mine, operated under lease by the Anaconda Copper Mining Co., reported a decrease of about 6,500,000 pounds in recovered zinc and 1,300,000 pounds in lead from zinc-lead ore. However, it showed a gain of about 5,500,000 pounds in zinc and 1,400,000 pounds in lead as a byproduct. In 1941 the Jack Waite mine in Sanders County made an increased output of zinc, but its production of lead decreased. The Flathead mine in Flathead County, operated by the Anaconda Copper Mining Co., reported a decreased output of lead. The Comet mine in Jefferson County showed a decrease in output of both metals, as operations were suspended in April 1941. The leading sources of zinc production in Montana in 1941 were the zinc mines of the Anaconda Copper Mining Co. at Butte, the fuming plant at East Helena, the Emma mine, the Emma byproduct zinc production, the Broadwater group in Cascade County, the Poulin mine in Silver Bow County, the Jack Waite mine in Sanders County, and the Mike Horse mine in Lewis and Clark County; these sources supplied 98 percent of the State total. The leading lead producers in Montana in 1941 were the zinc mines at Butte, the Jack Waite mine, the Flathead mine in Flathead County, the slag-fuming plant at East Helena, the Emma mine, the Broadwater mine, the Mike Horse mine, and the Emma byproduct lead output; these sources were credited with 84 percent of the State total.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Montana in 1941, by counties, in terms of recovered metals

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer	Fine ounces	Value	Fine ounces	Value

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

MINING INDUSTRY

Continuous operation of the zinc mines, the copper mines, and the Emma mine at Butte by the Anaconda Copper Mining Co. and increased production of zinc-lead ore from mines in Cascade, Lewis and Clark, and Granite Counties in 1941 maintained the output of copper, silver, and lead at substantially the same level as in 1940 and helped to increase the yield of zinc considerably above that in 1940. The chief gain in zinc output came from the slag-fuming plant at East Helena. Metals from ore treated at cyanidation and amalgamation mills and crude ore shipped to smelters showed a decline in 1941.

Declines of 2,536 fine ounces in gold and 1,620 fine ounces in silver were noted in the yield from placer mines. Seven connected-bucket floating dredges were in operation in 1941; they treated 9,025,755 cubic yards of gravel and recovered gold valued at $1,184,540, indicating an average recoverable gold value of 13.1 cents per cubic yard treated. Dragline and power shovels with both dry-land and floating washing plants were reported in operation at 40 properties. The plants washed 3,208,961 cubic yards of gravel and recovered gold valued at $886,305, indicating an average recoverable gold value of 27.6 cents to the cubic yard washed.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Montana in 1941, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	343	695, 481	140, 138	390, 639	243, 465	231, 558	-
Dry and siliceous gold-silver ore	76	121, 902	11, 277	700, 663	1, 608, 067	542, 782	-

[1] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.
[2] Includes 5,503,585 pounds recovered from precipitates
[3] Includes 170,592 tons of current slag fumed.
[4] Includes 5,624,886 pounds recovered from precipitates.

METALLURGIC INDUSTRY

The 5,642,249 tons of ore produced from Montana lode mines in 1941 were treated as follows: 99,482 tons at amalgamation plants, 443,388 tons at cyanidation mills, 4,661,117 tons at concentration mills, 267,670 tons shipped crude to smelters, and 170,592 tons treated at a slag-fuming plant.

Nine cyanidation mills treated 351,663 tons of gold ore, which contained 51,517 ounces of gold and 213,783 ounces of silver; the bullion and precipitates shipped contained 42,946 fine ounces of gold and 137,301 fine ounces of silver, indicating an average recovery of 83 percent of the gold and 64 percent of the silver. Nine mills treating 351,663 tons of gold ore reported the consumption of 190,718 pounds of sodium cyanide, 321,646 pounds of calcium cyanide, 55,087 pounds of zinc dust, and 2,839,780 pounds of lime

Ore treated at straight concentration plants increased from 4,101,902 tons in 1940 to 4,661,117 tons in 1941. The 1941 total comprised 155,034 tons of siliceous ores, 3,790,183 tons of copper ore, 8,545 tons of lead ore, 12,153 tons of zinc ore, and 695,202 tons of zinc-lead ore.

The East Helena smelter continued to operate throughout 1941 and treated ores and concentrates, chiefly from Montana and Idaho. The Anaconda electrolytic zinc plants, with four units at Anaconda and eight units at Great Falls, operated at an average capacity of about 2,575,000 pounds of zinc per unit per month, in terms of slab zinc, zinc dross, and zinc oxide. This rate was a 22-percent increase over that in 1940. Capacity at the plants in 1942 has been increased by adding additional tanks, and work is now under way to add the equivalent of one new unit at Anaconda and two units at Great Falls, which will increase the annual capacity of these plants to 465,000,000 pounds before the end of 1942.

Details of the treatment of all ores produced in Montana in 1941 are given in the tables that follow.

Mine production of metals in Montana in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated	99,482	7,938	2,508			
Ore cyanided	443,388	56,293	166,587			
Concentrates smelted [1]	662,594	60,046	10,102,389	247,705,376	29,513,047	83,918,000
Copper precipitates smelted	4,501			5,503,585		
Ore smelted	267,670	60,587	2,105,406	2,863,039	9,950,953	
Slag fumed	170,592				3,054,000	37,502,000
Placer		61,611	10,035			
		246,475	12,386,925	256,072,000	42,518,000	121,420,000
Total, 1940		272,602	12,361,050	252,782,000	46,072,000	105,174,000

[1] Includes zinc concentrates treated at electrolytic plants.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Montana in 1941, by types of mills and by counties, in terms of recovered metals

AMALGAMATION MILLS

County	Ore treated (short tons)	Recovered in bullion		Concentrates smelted and recovered metal

BEAVERHEAD COUNTY

Argenta district.—The Ermont Mines, Inc., operated the Ermont property throughout 1941 and produced most of the gold output in the Argenta district. The company operated its 100-ton countercurrent cyanide mill all year and treated 31,855 tons of gold ore of a lower grade than in 1940, resulting in a decline in gold output. Other important lode producers in the district were the Goldfinch and Shafer mines, which produced gold ore that was shipped crude to a smelter, and the Rosemont and Copper Bell properties, which produced crude lead ore. Some gold was recovered from the French Creek and Watson Gulch placers in 1941.

Bannack district.—Gold recovered from placer gravels made a marked gain in 1941 over that in 1940, but gold from lode mines a decided decrease. The main source of gold from lode mines in 1941 was crude gold ore shipped direct to a smelter from the New York-Montana and Gold Bug properties. The bulk of the placer gold output came from dredging by the Ralph E. Davis Syndicate on Grasshopper Creek. Equipment used comprised two draglines (one 5-cubic yard and one 1½-cubic yard) and a floating washing plant. During 1941 271,340 cubic yards of overburden were removed, and 131,035 cubic yards of gold-bearing gravel were washed, from which 2,690 ounces of gold were recovered. The Traderhorn Mining & Construction Co. operated a dry-land dredge in Dry Gulch for testing purposes. Several small sluicing operations, principally on Grasshopper Creek, recovered some gold.

Big Hole district.—Crude gold ore from the Star mine and crude lead ore from the S. S. & R. mine shipped direct to a smelter and gold ore from the North Star mine amalgamated comprised the metal output from lode mines in the Big Hole district in 1941. Some placer gold was recovered by sluicing.

Blue Wing district.—The output from the Blue Wing district in 1941 comprised shipments direct to smelters of several classes of crude ore, which included silver ore from the Federal Star, Del Monte, Silver Snow, and Single Jack properties, lead ore from the Ingersoll group, copper ore from the Cable claim, and gold ore from the Interstate property.

Bryant district.—Most of the output from the Bryant district in 1941 came from the Hecla mine and dump and consisted of 1,424 tons of crude gold-silver ore and 2,209 tons of gold-silver tailings shipped crude to smelters.

Colorado district.—The metal output of the Colorado district in 1941 was contained in lead ore shipped direct to a smelter from the H. & S. mine.

Horse Prairie district.—The bulk of the placer gold output from the Horse Prairie district in 1941 came from operations by W. C. McLeod on the Golden Leaf Placer on Jeff Davis Creek. The remainder came from operations by Associated Placers, Inc., on Jeff Davis and Horse Prairie Creeks. Both operators used dry-land dredges.

Vipond district.—The production from the Vipond district in 1941 comprised silver ore from the Lone Pine & Argyle and Aurora mines and lead ore from the Faithful mine, all shipped crude to smelters.

West Fork of Madison River district.—A dry-land dredge operated by Madison West Fork Placers supplied the placer gold output from the West Fork of Madison River district in 1941.

BROADWATER COUNTY

Backer district.—The value of the metal output from the Backer district in 1941 decreased from that in 1940, owing to a decline in placer gold production. Gold recovered by three dry-land dredges represented most of the output in 1941. The Pitcher Placer Mining Co. operated two draglines (1½ cubic yards and 1¾ cubic yards) on Boulder Bar in Confederate Gulch and handled about 90,000 cubic yards of gold-bearing gravel, averaging 23 cents in value of recoverable gold to the cubic yard washed. This operation was the largest in the district during 1941. Dry-land dredges were also operated by R. G. Woodard and C. J. Painter, both working in Confederate Gulch. The rest of the placer output came from small sluicing operations, chiefly in Confederate Gulch. Most of the lode output came from rich gold ore at the Superior mine.

Beaver district.—Lead ore rich in gold and containing considerable quantities of zinc was shipped crude to a lead smelter from the East Pacific and East Pacific Tunnel No. 4. This property, by far the most important producer in the district in 1941, was operated by lessees. The Iron Age property shipped 209 tons of crude gold ore, averaging over 2 ounces of gold to the ton, to a smelter in 1941. The 75-ton Custer flotation mill was idle in 1941, although a quantity of crude gold ore was shipped direct to a smelter from the Custer property. Other mines active in the Beaver district during 1941 included the Native Gold, which treated gold ore in a 25-ton flotation mill; the January, from which lead ore was shipped crude to a smelter; and the Kleinchmidt, from which crude silver ore was shipped direct to a smelter.

Cedar Plains district.—The value of the metal output from the Cedar Plains district in 1941 was virtually the same as in 1940. The M & M Mining Co., operating the Ohio Keating mine, was again the largest producer in the district and accounted for over 60 percent of the district total gold. In 1941 the daily capacity of the flotation mill was increased from 80 to 105 tons; in consequence, an average of 100 tons of gold ore a day was treated, producing over 6,000 tons of gold concentrates, which were shipped to a smelter. The C. G. Gold Corporation continued to operate its 100-ton flotation mill and made 3,000 tons of gold concentrates in 1941; in addition, a small quantity of gold ore was shipped direct to a smelter. Other production from the district included gold ore from the Robert E. Lee mine and lead ore from the Joe Dandy mine, all shipped crude to a smelter. Some placer gold was recovered from the Bald Eagle claim in Johnny's Gulch.

Park district.—The value of the metal production from the Park district in 1941 increased materially over that in 1940, owing entirely to the gain in output from placer operations by the Cooley Gravel Co. and Douglas Placers. The Cooley Gravel Co. operated from March to the middle of December 1941 and washed about 673,000 cubic yards of gold-bearing gravel from Indian Creek. The equipment consisted of a Bodinson all-electric floating washing plant, supplied with gravel by a 3-cubic yard dragline. The Douglas Placers, operating the Wilson Placers on Indian Creek, used two dragline excavators, which supplied gravel to a dry-land dredge. During 1941 the company washed approximately 500,000 cubic yards of gold-bearing gravel, which averaged 22 cents per cubic yard in value of recoverable gold.

The remainder of the placer output came from several small sluicing operations, principally on Indian Creek. The Marietta Mines shipped considerable lead ore and gold ore crude to smelters and produced most of the metal output from lode mines. Gold ore from the Little Giant mine and lead ore from the W. A. Clark mine shipped crude to smelters and gold ore amalgamated comprised most of the remaining district output in 1941.

CASCADE COUNTY

Montana district.—The Montana district showed a decided increase in output of silver, lead, and zinc in 1941 over 1940; it was the second-largest silver-producing district in the State. The Klies Mining Co., largest producer of lead and zinc in the district, operated throughout 1941. The 70-ton flotation mill was increased to 80-ton daily capacity and treated 29,120 tons of zinc-lead ore that contained about 150 ounces of gold, 150,000 ounces of silver, 20,000 pounds of copper, 2,200,000 pounds of lead, and 3,500,000 pounds of zinc. The concentration mill was operated 7 days a week, 3 shifts a day. The Lexington Mining Co. operated its 100-ton flotation mill the entire year and treated 32,718 tons of silver ore, which yielded most of the silver and gold output of the district. The Florence Mining Co. was active throughout 1941 and treated 14,664 tons of silver ore in its 75-ton flotation mill, which made lead concentrates. Lead ore from the Star group was treated in a 35-ton flotation mill by the New London Mining Corporation; the production totaled about 400 tons of lead concentrates. The Queen Leasing Co. operated its 60-ton flotation mill throughout 1941 and treated 18,500 tons of zinc-lead ore, which contained 77,700 ounces of silver, 555,000 pounds of lead, and 1,554,000 pounds of zinc. The property was closed in March 1942. Additional production from mines in the district included gold-silver ore from the Spotted mine, silver ore from the Benton group, and lead ore from the Champion "B," all shipped crude to a smelter.

DEER LODGE COUNTY

Georgetown district.—Gold ore from the Holdfast-Southern Cross group, treated by cyanidation, made up most of the output from the Georgetown district in 1941. The Sentinel Mines, Inc., working this group, operated its 65-ton countercurrent cyanidation mill throughout 1941 and treated 17,180 tons of ore. The metal output was somewhat less than in 1940. A small quantity of gold ore from the Cable mine was treated by amalgamation in 1941. The rest of the production from the district was gold ore shipped crude to a smelter; it came from several small producers, among which the Hub mine was the most important. A little placer gold was recovered from sluicing operations.

Heber district.—Gold ore from the Spain mine and a little gold from sluicing in First Chance Gulch comprised all the output from the Heber district in 1941.

Oro Fino district.—The output from the Oro Fino district in 1941 was crude silver ore shipped to smelters from the Champion and Cashier groups.

Silver Lake district.—Silver ore was shipped crude to smelters from the Silver Reef and Chloride Silver properties in 1941.

Smelter district.—Some copper ore clean-up and slimes from the Anaconda plant were shipped to Washoe.

FERGUS COUNTY

Cone Butte district.—Gold ore cyanided, from the Thomas and Old Glory mines, made up the output from the Cone Butte district in 1941.

North Moccasin district.—The North Moccasin Mines Syndicate treated 75,535 tons of gold ore from the Barnes-King open-cut mine by cyanidation in 1941. The ore contained 3,777 ounces of gold and 1,510 ounces of silver and yielded 2,715 ounces of gold and 1,080 ounces of silver. The cyanidation mill had a daily capacity of about 600 tons. A little placer gold was recovered from the Grubstake claim in 1941.

Warm Springs district.—The output from the Warm Springs district was copper ore from the Globe mine, gold ore from the Gold Crop mine, and silver ore from the Mickey mine, all shipped crude to smelters.

FLATHEAD COUNTY

Hog Heaven district.—The Flathead mine, owned and operated by the Anaconda Copper Mining Co., shipped 17,600 tons of silver ore and 14,926 tons of lead ore crude to smelters in 1941; it was one of the most important lead-producing mines in the State. The rest of the district production was contained in silver ore from the Birdseye mine and copper ore from the Flag-Martin mine, all of which was shipped crude to a smelter.

GALLATIN COUNTY

The output from Gallatin County in 1941 came from sluicing at the Jewel Placer in the Eldridge district.

GRANITE COUNTY

Alps district.—Most of the output from the Alps district in 1941 consisted of crude gold ore from the Rainy Day mine, shipped direct to a smelter.

Boulder district.—The Gold King mine, operated by lessees, was the chief producer in the Boulder district in 1941. Among other producers were the Apex mine, which shipped gold ore direct to a smelter, and the Saranac, which shipped zinc ore to the Anaconda zinc concentrator for treatment. Sluicing in Princeton Gulch recovered some gold.

Dunkleberg district.—Zinc-lead ore from the Forest Rose mine, treated by flotation concentration in a new 100-ton mill, comprised virtually all the output of the Dunkleberg district in 1941. The 100-ton mill, which was erected adjacent to the mine during the latter part of 1940, was put into operation on January 12, 1941, and continued for the remainder of the year. During this period it treated 18,766 tons of ore and made zinc concentrates and lead concentrates, which were shipped to Anaconda and East Helena smelters, respectively. The rest of the district output was gold-silver ore shipped crude to a smelter.

Flint Creek district.—Old tailings from the Granite-Bimetallic mine, operated by the Philipsburg Mining Co. in 1941, were again the chief

source of metal output from the Flint Creek district. The tailings were shipped direct to Tacoma and Washoe and there used chiefly for fluxing. The Kroger Lease of the Moorlight Mining Co. operated the Headlight mine and shipped 1,547 tons of gold-silver ore crude to a smelter, and the Moorlight Mining Co. operated the Climax mine and shipped lead smelting ore crude. Zinc-lead ore was shipped to the Anaconda zinc concentrator from the Silver Prince and Trout properties in 1941 by the Contact Mines Corporation and the Trout Mining Division of American Machine & Metals, Inc., respectively. In addition, the Contact Mines Corporation shipped a large quantity of silver ore crude to Washoe.

Gold Creek district.—The output from the Gold Creek district in 1941 was placer gold, nearly all of which was recovered by the Master Mining Co. from upper Gold Creek.

Henderson district.—The lode output of the Henderson district comprised silver ore from the Black Pine mine and dump and gold ore from the Sunrise mine. The placer gold output came from a dry-land dredge operated by H. J. Schneider & Bros. on the New Deal placer.

Maxville district.—Lead ore from the Blue Bird mine and gold ore from the Evergreen mine were shipped to East Helena in 1941.

Red Lion district.—The Red Lion Mining Co. cyanided gold ore from the Hidden Lake property and recovered most of the gold output of the Red Lion district in 1941. The rest of the output was crude gold smelting ore from the Lila Dixon and Surprise groups.

Rock Creek district.—The Normac Corporation built a 25-ton cyanide plant during 1941 and treated some gold ore from the Ella mine. Other lode production from the Rock Creek district was gold ore from the Shakespeare mine. Some placer gold was recovered.

JEFFERSON COUNTY

Amazon district.—Lead ore was shipped crude to a smelter in 1941 from the East Mint mine and the Anna Carmen dump.

Bigfoot district.—A small lot of gold ore from the Grass Root property was shipped to a smelter in 1941.

Boulder district.—Ore was shipped crude to a smelter in 1941 from several properties in the Boulder district, including gold-silver ore from the Adolphus, silver ore from the Baltimore, and lead ore from the Ing, Esperanzie, and St. John properties. Some gold was produced from placers near Boulder.

Cataract district.—The total value of the metal output of the Cataract district in 1941 decreased materially from 1940, owing almost entirely to the closing of the Comet property by the Basin Montana Tunnel Co., in April 1941. As commercial ore was exhausted, the 200-ton flotation mill on the property was idle for the remainder of 1941. The Boulder, Bullion, Crystal, Deer Lodge, Morning Glory, and Red Eagle mines were among the other lode producers in the district in 1941. Some gold was recovered by sluicing near Boulder.

Clancey district.—The metal output from the Clancey district in 1941 again came largely from placer operations. The Winston Bros. Co. continued to operate its 6-cubic foot electrically powered Yuba dredge throughout 1941. The dredge handled 2,157,277 cubic yards of gravel compared with 1,880,436 in 1940. The company again was the leading placer gold producer in Montana. The Williams Construction Co., operating a dry-land dredge near Clancey, ranked second.

The Jefferson Placers and O. A. Barnes operated dry-land dredges on Clancey Creek and Holmes Creek, respectively. A total of 28,700 cubic yards of gravel was washed, which averaged about 75 cents in value of recoverable gold per cubic yard. The remainder of the placer production in the district came from sluicing, chiefly in Lump Gulch. The lode production was ore shipped crude to smelters; it came from the Frohner, Our Ticket 45, Panama, and Paragraph mines.

Colorado district.—Eathorne & Fox, again the leading producers in the Colorado district, treated zinc-lead tailings from the Alta dump in 1941. The mill, which treated 29,607 tons of tailings in 1941, made 1,391 tons of lead concentrates and 40 tons of zinc concentrates. The Blue Bird mine shipped crude to Washoe 2,038 tons of gold-silver ore containing 714 ounces of gold and 20,884 ounces of silver. Other mines active in 1941 included the Buckeye, Blizzard, Custer, and Pen Yan.

Elkhorn district.—The only production in the Elkhorn district in 1941 was lead ore and gold ore shipped crude to smelters from the C & D, Elkhorn, Klondyke, and Little Goldie mines.

Golconda district.—The output from the Golconda district in 1941 was gold, silver, and lead ores shipped crude to smelters.

Homestake district.—Gold and gold-silver ore shipped direct to smelters formed the lode mine output in 1941. The Payrock mine was the largest producer. Some gold was recovered by sluicing on Betty Creek.

Lowland district.—Placer gold comprised the bulk of the output from the Lowland district in 1941, and the Kit Carson Placers produced virtually the entire output. The company operated a dry-land dredge from May through September and washed 170,000 cubic yards of gold-bearing gravel, which averaged 22 cents per cubic yard in recoverable gold. In addition, the company removed 354,000 cubic yards of overburden preparatory to dredging. Lode production came from the Montreal and Infinite groups.

Mitchell district.—Gold ore shipped crude to smelters was the output from the Mitchell district in 1941.

Warm Springs district.—Gold-silver ore was shipped crude to a smelter from the Greenleaf dump in 1941.

Whitehall district.—The Golden Sunlight mine, operated by lessees, was the largest producer in the Whitehall district in 1941; it shipped 5,105 tons of gold ore containing 3,075 ounces of gold and 4,142 ounces of silver. Among the other producers were the Florence, Lucky Hit, Ivans, and Sunny Corner mines.

Willow Creek district.—The output from the Willow Creek district in 1941 was lead ore shipped crude to a smelter and gold ore amalgamated and concentrated from the Callahan group (Deer Horn).

JUDITH BASIN COUNTY

Barker district.—The output of the Barker district in 1941 was lead ore shipped crude to East Helena from the Glendennin group and the Marcelline and Silver & Bell mines.

Yogo district.—Gold ore from the Gold Bug mine and copper ore from the Blue Dick mine, shipped crude to Washoe, comprised the only output in the Yogo district in 1941.

LEWIS AND CLARK COUNTY

Blue Cloud district.—One lot of lead ore was shipped to East Helena from the Lincoln mine in 1941.

Dry Gulch district.—The Golden Messenger mine was operated throughout 1941 by the Golden Messenger Corporation. The output was about 50,000 tons of gold ore cyanided in the company 150-ton mill. The bullion produced yielded 7,307 ounces of fine gold and 6,030 ounces of fine silver. The property was closed in March 1942. A little placer gold was recovered by sluicing.

Heddleston district.—The value of the metal output of the Heddleston district in 1941 increased substantially over that of 1940, owing entirely to work by the Mike Horse Mining & Milling Co. The company operated its 150-ton flotation mill throughout 1941 except for the months of April, May, and June. During the operating period, about 27,000 tons of zinc-lead ore were treated, producing about 1,500 tons of lead concentrates and 1,300 tons of zinc concentrates. Production figures based upon the first quarter of 1942 indicate that the property is exceeding its 1941 rate. Other producers in the district were the Carbonate, Mazuma, and Consolation mines.

Helena district.—Placer gravel remained the chief source of mineral value in the Helena district in 1941. By far the largest part of the placer gold output came from dredging by Porter Bros. Corporation. The 6-cubic foot electric-powered bucket dredge operated throughout 1941 in Last Chance Gulch near Helena and treated 1,864,078 cubic yards of gravel. A small dry-land dredge was operated on the Travis Placer from April to the middle of May. The rest of the placer gold output came from several small sluicing operations. The lode output came from several small lode mines; the most important were the Court House, Whitlatch, and Spring Hill.

Jefferson Gulch district.—A little placer gold was recovered by sluicing in Jefferson Gulch.

Lincoln district.—Placer gold contributed the major part of the metal output from the Lincoln district in 1941; it was recovered by sluicing, principally in Lincoln, McClellan, and Sauerkraut Gulches. The lode output came from gold ore amalgamated and gold ore shipped crude to smelters.

Marysville district.—Lode mines produced the bulk of metal values from the Marysville district in 1941. The Martin Mining Co., again the leading producer, treated 36,350 tons of old tailings from the Eck mine in its 125-ton roasting and cyaniding mill. The tailings were excavated by power shovels and trucked about 1 mile to the mill. The J. C. Archibald Co. treated old tailings from the Bald Butte mine, but the quantity of gold recovered was less than in 1940. Lessees operated the Shannon group and shipped crude to Washoe 743 tons of gold ore, which contained 606 ounces of gold and 403 ounces of silver. Several groups of lessees operated the St. Louis Drumlummon mine in 1941 and shipped gold ore crude to smelters. The Rex Mining Co. treated gold-silver ore in its 35-ton flotation mill and made 71 tons of lead concentrates. Among the other producers in the district were the Penobscot mine, Piegan-Gloster group, and Golden Gate mine.

Missouri River district.—The Perry-Schroeder Mining Co. continued to operate its 6-cubic foot electrically driven Yuba dredge on the

Missouri River 15 miles north of Helena throughout 1941 and handled 1,873,400 cubic yards of gold-bearing gravel.

Ophir Gulch district.—Gold ore was shipped crude to a smelter from the Nora Darling mine in 1941.

Rimini district.—The bulk of the lode production in the Rimini district in 1941 came from the Armstrong mine, which shipped lead ore crude to East Helena. The rest of the lode output of the district was ore shipped crude to smelters, chiefly from the Eureka and Porphyry Dike mines. A dry-land dredge, operated by N. Rogers on the Gould Placer near Rimini in 1941, contributed the major part of the placer gold output.

Scratch Gravel district.—Ore shipped crude to a smelter from the Franklin and Julia mines and gold ore amalgamated from the Umatilla mine comprised the output from the Scratch Gravel district.

Silver City district.—The output from the Silver City district was old tailings amalgamated from the Albert Brown mine.

Smelter district.—The fuming plant owned by the Anaconda Copper Mining Co. continued throughout 1941 to treat slag from the lead smelter of the American Smelting & Refining Co. at East Helena. The value of the zinc fume produced was $1,250,130 greater than that produced in 1940.

Stemple district.—The Gould mine operated by the Standard Silver-Lead Mining Co. again produced the bulk of the output in the Stemple district. In 1941, 27,871 tons of ore and old tailings were cyanided in the 75-ton cyanide plant. The bullion shipped to the Seattle Assay Office contained 4,720 ounces of fine gold and 20,137 ounces of silver. Among other mines active in the Stemple district in 1941 were the New Silver Bell, Bachelor, Homestake, and Hubbard. A little gold was recovered by sluicing, principally in Canyon Creek.

LINCOLN COUNTY

Libby district.—The Courageous Mining Co. treated 17,239 tons of gold ore from the Branagan mine in its 150-ton amalgamation and flotation-concentration mill. The Glacier Silver-Lead Mining Co. milled 6,443 tons of gold-silver ore from the Lukens Hazel mine, which made 142 tons of lead concentrates. The Snowshoe Mines, Inc., treated zinc-lead ore in its 100-ton flotation mill; it made 162 tons of lead concentrates and 31 tons of zinc concentrates. Two other mills active in the Libby district in 1941 were the 50-ton Midas mill, which treated gold ore from the Midas mine, and the 25-ton Tip Top mill, which treated gold ore from the New Deal property. The rest of the lode output was lead ore from the Silver Butte and gold ore from the Merrie claim, all shipped crude to smelters. Some gold was recovered by sluicing, chiefly on Libby Creek.

MADISON COUNTY

Norris district.—The Boaz mine operated its 50-ton cyanide and concentration mill throughout 1941 and treated both company and custom gold ore. The mill treated 13,415 tons of gold ore from company properties, which yielded 5,145 ounces of gold and 3,178 ounces of silver in bullion and 1,879 ounces of gold and 806 ounces of silver in gold concentrates. The Grubstake mine, second-largest producer in the Norris district, shipped about 500 tons of rich gold ore to Washoe

in 1941. The Revenue mine operated only the first part of 1941 but ranked third in lode gold output in the district. Among other lode mines making sizable production in 1941 were the Madisonian, Heleene, New York Belle, and Emperor. Nearly the entire placer output from the district in 1941 came from the operation of a bucket dredge on the Norwegian Placer by Homer Wilson. The dredge is equipped with 5-cubic foot buckets and washed 150,000 cubic yards of gravel, from which 1,490 ounces of fine gold were recovered—a slight increase over 1940.

Pony district.—The output of the Pony district decreased sharply in 1941 from 1940, owing chiefly to inactivity of the Atlantic-Pacific group. The bulk of the output in 1941 came from the Mammoth mine, from which 17,585 tons of gold ore were concentrated, making copper concentrates containing 3,460 ounces of gold, 5,646 ounces of silver, and 80,353 pounds of copper. Among the other producers in the district were the Boss Tweed & Clipper and Ridgeway mines. A little placer gold was recovered by sluicing.

Renova district. — The West Mayflower mine, owned and operated by the Anaconda Copper Mining Co., was again the largest gold producer in Montana; in 1941 it produced 19,166 tons of gold ore shipped crude to Washoe and containing 19,760 ounces of gold and 135,026 ounces of silver. The Mary Ingaber mine was operated by lessees.

Rochester (Rabbit) district.—The Lively Mining Co., operating the Hidden Treasure mine, was the largest producer in the Rochester district during 1941. Ore was shipped direct to smelters from several small mines.

Ruby Creek district.—A dry-land dredge recovered some gold in 1941 from tests on Gumbo Flats.

Sheridan district.—The Sheridan Gold Mining & Milling Co., operating the Uncle Sam, Toledo group, and Occidental properties in 1941, was again the largest producer in the Sheridan district. Gold ore was shipped crude from the Uncle Sam and Occidental mines, and lead ore was shipped crude from the Toledo group. Production was reported from 27 other lode mines in the district. The Traderhorn Mining & Construction Co. produced most of the placer gold recovered in the district in 1941. The company tested the Sievers Placer in California Gulch and used a dry-land dredge.

Silver Star district.—The Victoria Mines, Inc., operated the Broadway mine and its 125-ton cyanide plant throughout 1941. The company treated 39,273 tons of gold ore in its mill and in addition shipped 654 tons of gold ore crude to smelters. The Green Campbell property, operated by the Green Campbell Mining Co., ranked second in gold output in the Silver Star district. During 1941 the company treated 6,731 tons of gold ore in its 25-ton amalgamation-concentration mill; this ore yielded 202 ounces of gold in amalgamation bullion and 988 ounces of gold in gold concentrates. The Golden Rod Mining Co. shipped crude to a smelter 490 tons of gold ore, which averaged over 2 ounces of gold to the ton. Among the other lode producers in the district in 1941 were the Aurora and Edgerton, both shipping gold ore crude to Washoe.

Tidal Wave district.—The metal output of the Tidal Wave district in 1941 came from several small lode mines and was mostly gold ore shipped crude to smelters. The most important producers were the High Ridge mine, Pollinger group, and Smith and Agitator mines.

Virginia City district.—There were 34 lode mines active in the Virginia City district in 1941. The five leading mines—East & West Mapleton, Bartlett, and Alameda mines and the Prospect and Easton-Pacific groups—produced an aggregate of 10,203 tons of gold and gold-silver ore, which contained 3,247 ounces of gold and 41,110 ounces of silver. Among the other leading producing lode mines were the U. S. Grant, Apex, Gold Bar, Marietta, and St. John properties. The Howe Dredging Co. was the largest producer of placer gold in the district in 1941. The equipment consisted of a dry-land dredge, and during 1941 about 20,000 cubic yards of gravel were washed. Several sluicing operations also were active in the district, of which the most important were the E. D. Howe operation in Wisconsin Gulch and the G. Gosta Miller operation in Cottonwood Creek.

Washington district.—The Gold Creek Mining Co. operated its floating connected-bucket dredge for 9 months of 1941 and recovered 1,785 fine ounces of gold from 499,010 cubic yards of gravel. The dredge is electrically powered and has sixty-two 4½-cubic foot buckets. The lode production in the Washington district came from gold ore shipped direct to a smelter, principally from the Missouri McKee mine.

MEAGHER COUNTY

Beaver Creek district.—The output from the Beaver Creek district in 1941 came mostly from operations of three dry-land dredges. The largest producer was the dredge operated by the T. C Mines on Thomas Creek which handled 21,400 cubic yards of gravel and recovered 112 ounces of gold.

Camas Creek district.—Some gold was recovered by sluicing.

Carbonate district.—Some copper ore was shipped direct to a smelter from the Peterson Waite mine.

MINERAL COUNTY

Cedar Creek district.—The bulk of the placer gold output in the Cedar Creek district in 1941 came from dry-land dredging by the Superior Mines Co. The rest came from several small sluicing operations.

MISSOULA COUNTY

Coloma district.—Gold ore shipped crude to smelters was the chief source of metal output in the Coloma district in 1941. The Mammoth & East Mammoth, Dixie, and Dandy mines were the chief producers.

Copper Cliff district.—Gold ore from the Copper Cliff mine was the only output from the Copper Cliff district in 1941.

Elk Creek district.—A little placer gold was recovered by sluicing.

Nine Mile district.—The Weaver Dredging Co. operated a dragline dredge on Nine Mile Creek from March to May 19; on May 19, this company was dissolved and the Beaver Dredging Co., a partnership, resumed the operations. The new partnership also operated a dry-land dredge on Nine Mile, Josephine, and McCormick Creeks. In all, 506,187 cubic yards of gold-bearing gravel from these operations were treated; 2,858 fine ounces of gold were recovered. The rest of the placer gold output was from sluicing, mainly on McCormick Creek.

PARK COUNTY

Emigrant Creek district.—The Emigrant Dredging Co. operated a floating electrically powered connected-bucket Yuba dredge, equipped with 110 10-cubic foot buckets, in Emigrant Gulch from August 15 to December 31, 1941; as a result, the output from the Emigrant Creek district increased sharply over 1940. During its period of activity the dredge washed 558,000 cubic yards of gravel. The remaining district output came from several small sluicing operations.

New World district.—The McLaren Gold Mines Co., operating the Estelle property throughout 1941, milled 19,000 tons of gold ore, which made 675 tons of copper concentrates, containing about 6,500 ounces of gold, 5,000 ounces of silver, and 103,000 pounds of copper. The capacity of the mill was increased to 200 tons a day, and in 1942 the production is expected to reach 1,000,000 pounds of copper in concentrates containing substantial quantities of gold. The Irma Mines, Inc., treated zinc-lead ore in its 30-ton flotation mill and produced lead and zinc concentrates. In addition, the company shipped 164 tons of lead ore crude to East Helena. Some placer gold was recovered by sluicing.

Sheepeater (Jardine) district.—The Jardine Mining Co. operated the Jardine mine all of 1941. The company amalgamation and concentration mill treated 69,324 tons of gold ore, from which 7,436 ounces of gold were recovered. Gold ore shipped crude to a smelter totaled 145 tons. Extra equipment was installed in the mill during 1941, and surface mining was adopted in addition to underground mining.

PHILLIPS COUNTY

Little Rockies district.—The Ruby Gulch Mining Co. operated the Ruby Gulch mine throughout 1941 and treated 94,244 tons of gold ore by straight cyanidation. The 300-ton cyanide mill was operated at capacity all year. The Little Ben mine produced 24,847 tons of gold ore, which was cyanided by the Little Ben Mining Co. in its 150-ton mill. The mill was operated in 1941 at the rate of two shifts a day for 5 months and one shift a day for 7 months.

POWELL COUNTY

Big Blackfoot district.—The Western Montana Gold Mining Co. operated the Blackfoot Group intermittently during 1941, treated gold ore in its 30-ton concentration mill, and also shipped gold ore crude to Washoe. Other lode production in the Big Blackfoot district included gold ore amalgamated from the Sweepstake mine. Placer gold was recovered by sluicing on McCormick Creek.

Nigger Hill district.—Gold-silver ore concentrated from the Old Monarch mine represented virtually all the lode output from the Nigger Hill district in 1941. Some placer gold was recovered by sluicing.

Ophir district.—Gold ore smelted from the Victory claim and placer gold recovered from several small sluicing operations comprised the output from the Ophir district in 1941.

Pioneer district.—The bulk of the output in the Pioneer district in 1941 came from hydraulic operations by Francis Slaughtner and dry-land dredging operations by the Master Mining Co., both at Gold Creek. The Pioneer Placer Dredging Co. did not resume operations

after closing down in 1940. Some lead ore was shipped crude to East Helena.

Washington Gulch district.—A dry-land dredge operated on the Peacock Placer in Washington Gulch in 1941. Gold ore was shipped crude from the Grey mine to a smelter.

Zozell (Emery) district.—Crude gold, gold-silver, and lead ores from the Bonanza and Emery Consolidated mines contributed the bulk of the metal output of the Zozell district in 1941. In addition, the Emery Consolidated shipped zinc-lead ore to the Midvale concentrator in Utah. Other important producers were the Blue-Eyed Maggie, Emma Darling, and Hidden Hand mines; all shipped ore crude to smelters in 1941.

RAVALLI COUNTY

Curlew district.—The output from the Curlew district in 1941 came from the Curlew mine. Zinc ore was concentrated and over 500 tons of zinc concentrates were shipped to a smelter.

Overwich district.—The J. L. Shiely Co. operated a dragline dredge from March 27 to November 30, washed 376,920 cubic yards of gravel, and recovered 2,237 fine ounces of gold. The equipment comprised a Bodinson floating washing plant and a 2½-cubic yard dragline. Some gold ore from the Washington mine was amalgamated.

SANDERS COUNTY

Eagle district.—The Jack Waite mine extends over the State line into Idaho. The property was operated throughout 1941 by the American Smelting & Refining Co. During this period the company treated (in its 300-ton flotation mill) 25,967 tons of zinc-lead ore containing 27,006 ounces of silver, 5,395,943 pounds of lead, and 2,783,662 pounds of zinc; the concentrates produced amounted to 3,136 tons of lead concentrates and 2,195 tons of zinc concentrates. In addition, 1,256 tons of lead ore, which contained about 1,775,000 pounds of lead and 7,585 ounces of silver, were shipped crude to East Helena.

Revais Creek district.—Copper ore from the Drake property was concentrated in 1941 by the Green Mountain Mining Co. in its 50-ton flotation mill. In addition to the concentrates produced, 118 tons of copper ore, containing 19 ounces of gold, 136 ounces of silver, and 34,451 pounds of copper, were shipped direct to Washoe.

Other districts.—Production was reported from the Dog Lake mine in the Plains district, the Ambassador mine in the Trout Creek district, and the Shoestring No. 1 and No. 2 and Razorback mines in the Vermillion district.

SILVER BOW COUNTY

The total value of the metal output from mines in Silver Bow County in 1941 gained $3,324,006 over 1940; all metals except lead made gains, owing to increased production of copper and zinc-lead ores at Butte. The following table gives the output of mines in Silver Bow County, which includes the Butte or Summit Valley district, in 1940 and 1941 and the total from 1882 to the end of 1941.

Production of gold, silver, copper, lead, and zinc in Silver Bow County, Mont., 1940–41, and total, 1882–1941, in terms of recovered metals

	Mines producing	Ore (short tons)	Gold (lode and placer) (fine ounces)	Silver (lode and placer) (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value
1940	58	3,764,610	25,107	8,766,398	250,884,000	17,718,500	71,798,000	$40,871,719
1941	50	4,421,641	29,485	8,993,693	254,863,000	17,260,900	76,140,400	44,195,725
1882–1941	----	(1)	1,952,811	517,777,237	(2) 6,006,680	(2) 215,736	(2) 1,509,891	2,418,107,139

[1] Figures not available.
[2] Short tons.

Butte or Summit Valley district.—All productive mines of the Anaconda Copper Mining Co. at Butte were brought up to capacity during 1941, with the result that the output of all metals but lead increased. Lead production was slightly less than in 1940. In 1941, 2,869,051 tons of copper ore were sent to the copper concentrator at Anaconda compared with 2,737,572 tons in 1940, and 4,500 tons of mine-water precipitates were treated compared with 3,812 in 1940. In addition, the copper concentrator at Anaconda treated 405,862 tons of mine-dump material averaging about 1 percent copper and 512,930 tons of Old Works tailings and Upper Old Works tailings averaging slightly over 1 percent copper. Crude ore smelted totaled 36,596 tons, and tailings 32,881 tons. All zinc mines of the Anaconda Copper Mining Co. operated throughout 1941; the output consisted of 472,133 tons of zinc-lead ore treated at the Anaconda zinc concentrator compared with 362,479 tons in 1940. Development comprised at the copper mines 210,045 feet of drifts, 1,492 feet of shafts, and 20,599 feet of diamond drilling; at all zinc mines, 27,653 feet of drifts, 772 feet of shafts, and 2,414 feet of diamond drilling. Operations were continued throughout 1941 at the Emma mine, leased from the Butte Copper & Zinc Co. by the Anaconda Copper Mining Co. The production—36,329 tons of zinc-lead ore compared with 77,353 tons in 1940—was treated at the Anaconda zinc concentrator. The output of the company included 12,193 tons of zinc-lead sulfide concentrates (zinc-lead middlings). The sulfide concentrates were re-treated at the Anaconda zinc concentrator.

Lessees of the Anaconda Copper Mining Co. operated several company properties; the most productive were the Poulin, which produced over 3,000,000 pounds of zinc, and the Black Rock group, which produced 9,973 tons of silver ore.

Divide Creek district.—Small lots of silver ore were shipped crude to Washoe in 1941.

Highland district.—The Butte Highlands Mining Co. operated the Highlands group (Tilton) in 1941 and treated 18,339 tons of gold ore in its 75-ton cyanide plant. The ore yielded 6,317 ounces of gold and 517 ounces of silver.

Independence district.—Silver ore was shipped crude to Washoe from the Deadwood and Goldflint mines in 1941.

Melrose district.—Small lots of silver ore were shipped from the Galla Nipper and Olson properties in 1941.

Silver Bow Creek district.—Some gold was recovered from sluicing on Silver Bow Creek in 1941.

STILLWATER COUNTY

Placer gold was recovered by sluicing in the Gold Butte district in 1941.

TOOLE COUNTY

Yellowstone River district.—A dry-land dredge operated on gravel bars along the Yellowstone River in 1941 and recovered some gold.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEVADA

(MINE REPORT)

By Charles White Merrill and H. M. Gaylord

SUMMARY OUTLINE

SUMMARY

The total value of gold, silver, copper, lead, and zinc recovered from ores, old tailings, and gravels in Nevada in 1941—$38,959,420—was greater than in any year since 1918 (see fig. 1). Gold production decreased in 1941 compared with 1940, but both quantity and value of each of the other four metals increased. Copper production—157,822,000 pounds—exceeded all years but 1928, which was greater by only 1,054,883 pounds. Gold decreased 5 percent in both quantity and value; silver increased 13 percent in both quantity and value, copper 1 percent in quantity and 5 percent in value, lead 28 percent in quantity and 46 percent in value, and zinc 28 percent in quantity and 52 percent in value. The total value of the five metals was 5 percent greater than in 1940; of this total value, copper comprised 48 percent, gold 33, silver 10, zinc 6, and lead 3 percent.

White Pine County continued in 1941 to be the largest contributor to the mineral output of the State; it ranked again first in copper and second in gold and was third in silver. Humboldt County was again the leading gold producer. Lincoln County led in silver and again in lead and zinc.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052
1940	35.00	[6] .711+	.113	.050	.063
1941	35.00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+ ($20.671835) per fine ounce.

[2] 1937: Yearly average weighted Treasury buying price for newly mined silver, 1938-41 Treasury buying price for newly mined silver.

[3] Yearly average weighted price of all grades of primary metal sold by producers.

[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Nevada, 1937–41, and total, 1859–1941, in terms of recovered metals

[1] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property

[2] Compiled by Chas W. Henderson, supervising engineer, field offices, Denver, Colo. From 1904 (when first satisfactory annual canvass of mine production was made) to 1941, inclusive, the output was as follows: Gold, 12,948,569.51 ounces, valued at $301,219,053, silver, 292,293,481 ounces, $197,120,178, copper, 1,463,568 tons, $419,847,894, lead, 279,168 tons, $32,471,821, zinc, 258,839 tons, $35,463,284, total value, $986,122,230.

[4] Short tons.

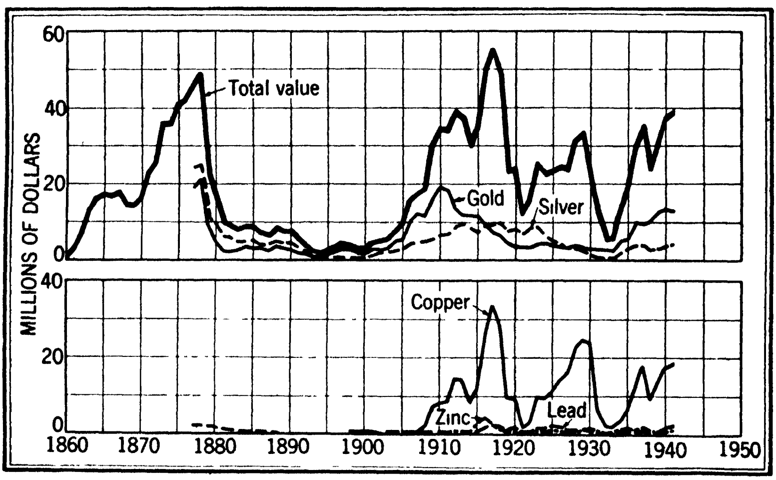

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc and total value in Nevada, 1860–1941

Gold.—Almost three-fourths of the recoverable gold output of Nevada in 1941 was derived from dry ores, chiefly gold ore, and virtually all the gold from base-metal ores came from copper ore; placer gold constituted 10 percent of the total. Five companies produced 45 percent of the State total gold, and the 10 leading gold-producing mines listed in the following table supplied 60 percent. Five of the

mines listed (Getchell, Manhattan dredge, Northumberland, Gold Standard, and Dayton dragline dredge) have begun production since March 1, 1938; together they produced 32 percent of the State total in 1941.

Ten leading gold-producing mines in Nevada in 1941, in order of output

Rank	Mine	District	County	Rank in 1940	Operator	Source of gold
1	Getchell	Potosi	Humboldt	1	Getchell Mine, Inc.	Gold ore.
2	Ruth and Copper Flat Pit.	Robinson	White Pine	3	Nevada Consolidated Copper Corporation.	Copper ore.
3	Coppermines group.	do	do	2	Consolidated Coppermines Corporation.	Do.
4	Manhattan dredge	Manhattan	Nye	4	Manhattan Gold Dredging Co.	Dredge.
5	Mary	Silver Peak	Esmeralda	5	Prescott Lease (E. L. Cord)	Gold ore.
6	Gold Standard	Imlay	Pershing	8	Standard Cyaniding Co.	Do.
7	Northumberland	Northumberland	Nye	7	Northumberland Mining Co	Do.
8	Overman	Comstock	Storey	9	Consolidated Chollar Gould & Savage Mining Co.	Do.
9	Dayton dredge	Silver City	Lyon	(1)	Dayton Dredging Co.	Dragline dredge.
10	Keystone	Comstock	Storey	6	Dayton Consolidated Mines Co. and lessees.	Gold ore.

[1] Operation began Jan. 1, 1941.

Silver.—The 10 leading silver-producing mines in Nevada in 1941, listed in the following table, produced 57 percent of the State total recoverable silver; the first 2 yielded almost one-fourth of the total. As in preceding years, most of the silver was a byproduct of ore mined chiefly for other metals; only 21 percent was derived from straight silver ore.

Ten leading silver-producing mines in Nevada in 1941, in order of output

Rank	Mine	District	County	Rank in 1940	Operator	Source of silver
1	Nivloc	Silver Peak	Esmeralda	1	Desert Silver, Inc.	Silver ore.
2	Pioche Nos. 1 and 2.	Pioche	Lincoln	2	Combined Metals Reduction Co.	Zinc-lead ore.
3	Pansy Lee	Barrett Springs	Humboldt	25	West Coast Mines, Inc.	Gold-silver ore.
4	Mizpah	Tonopah	Nye	3	Various lessees	Do.
5	Bristol Silver	Jack Rabbit	Lincoln	9	Bristol Silver Mines Co.	Lead ore.
6	Dan Tucker	Sand Springs	Churchill	4	Summit King Mines, Ltd.	Gold-silver ore
7	El Dorado-Rover group.	Eldorado Canyon.	Clark	6	El Dorado-Rover Mining Co.	Do.
8	Crown Point	Comstock	Storey	7	Sutro Tunnel Coalition, Inc.	Do
9	Overman	do	do	8	Consolidated Chollar Gould & Savage Mining Co.	Gold ore.
10	Gore	Taylor	White Pine	54	Various lessees	Silver ore.

Copper.—Nearly 99 percent of the recoverable copper output of Nevada in 1941 came from mines operated by the following companies: The Nevada Consolidated Copper Corporation, working the Ruth mine at Ruth and the open pit at Copper Flat (in the Robinson district, White Pine County); the Consolidated Coppermines Corporation, working the Coppermines group at Kimberly (also in the Robinson district); and the Mountain City Copper Co., working the Mountain City mine at Mountain City (in the Cope district, Elko County).

Lead and zinc.—The Combined Metals Reduction Co. in the Pioche district, Lincoln County, produced 92 percent of the recoverable zinc and 63 percent of the recoverable lead output of Nevada in 1941.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Nevada in 1941, by counties, in terms of recovered metals

County	Mines producing [1]		Gold						Silver (lode and placer)	
			Lode		Placer		Total			
	Lode	Placer	Fine ounces	Value	Fine ounces	Value	Fine ounces	Value	Fine ounces	Value

[1] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

MINING INDUSTRY

Expansion of production at the three large copper mines in Nevada in 1941 explains most of the increase in tonnage of ore treated compared with 1940. Production of copper ore and of dry and siliceous ore each increased 11 percent. Cessation in 1940 of old-tailings cyanidation by the Bradshaw Syndicate, Inc., in the Goldfield district,

Esmeralda County, and the Caliente Cyaniding Co. in the Ferguson district, Lincoln County, terminated the large-scale working of old tailings in the State; the quantity of old tailings treated declined 98 percent in 1941 compared with 1940.

The connected-bucket dredge of the Manhattan Gold Dredging Co. in the Manhattan district, Nye County, was again the largest producer of placer gold and the fourth-largest of total gold in the State; the dragline operation started January 1, 1941, by the Dayton Dredging Co. made the second-largest placer-gold and the ninth-largest total-gold output in the State in 1941. In addition to these large placer operators, 2 dragline dredges, 6 nonfloating washing plants with mechanical excavators, 1 hydraulic mine, 52 (24 dry) small-scale hand-method mines, and 15 drift mines were in operation. Quicksilver consumption at placer mines was 405 pounds in 1941.

ORE CLASSIFICATION

The following table classifying ores produced in Nevada in 1941 shows that 78 percent of the tonnage of ore (including old tailings) sold or treated was copper ore, 14 percent gold ore and old tailings, 5 percent gold-silver ore and old tailings, nearly 2 percent zinc-lead ore, 1 percent silver ore and old tailings, and the remainder lead ore and old tailings and zinc ore.

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore and old tailings sold or treated in Nevada in 1941, with content in terms of recovered metals

Source	Material sold or treated		Gold	Silver	Copper	Lead	Zinc
	Ore	Old tailings

METALLURGIC INDUSTRY

Of the 8,799,635 tons of lode material from Nevada sold or treated during 1941, 80 percent went to concentrating mills, 18 percent to amalgamation and cyanidation mills, and 2 percent to smelters; of the total, only 0.1 percent was old tailings—all amalgamated, cyanided, or smelted. Flotation was employed at concentration mills to the virtual exclusion of gravity concentration. Of the gold recovered as

bullion, cyanidation supplied 88 percent and amalgamation 12 percent; of the silver recovered as bullion, 99 percent was derived by cyanidation and 1 percent by amalgamation. The total quantity of crude ore shipped to smelters in 1941 was virtually unchanged from 1940. The Combined Metals Reduction Co., Pioche district, Lincoln County, began to operate its 600-ton selective-flotation mill in September 1941; the mill was laid out so that capacity could be tripled by the addition of two more grinding and flotation units. Operation of the new 150-ton flotation mill built by the West Coast Mines Co., Inc., in the Barrett Springs district, Humboldt County, was begun February 1. Construction of a 350-ton flotation mill by the International Smelting & Refining Co. in the Battle Mountain district, Lander County, neared completion at the end of 1941. Fire destroyed the Black Mammoth 150-ton cyanide mill in the Silver Peak district, Esmeralda County, September 23, 1941.

Quicksilver consumption in Nevada in 1941 at mills using amalgamation was 2,490 pounds in recovering 25,757 ounces of gold and 19,120 ounces of silver from 250,702 tons of material treated.

Data obtained on cyanide consumption in 1941 at Nevada mills are nearly complete. In the treatment of 1,202,361 tons of ore, 1,500 tons of old tailings, and 344 tons of concentrates, 290,182 pounds of 91-percent sodium cyanide and 1,782,513 pounds of commercial-grade calcium cyanide (50-percent NaCN equivalent) were used, with a recovery of 166,936 ounces of gold and 1,841,537 ounces of silver; in terms of 98-percent NaCN the consumption was 1,178,900 pounds, or 0.98 pound to the ton of material treated compared with 0.74 pound in 1940 and 0.64 pound in 1939. The declining proportion of old tailings treated explains the rising average consumption of cyanide in the State.

Mine production of metals in Nevada in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc
	Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*
Ore and old tailings amalgamated	250,702	25,757	19,120

		366,403	5,830,238	157,822,000	19,246,000	30,258,000
Total, 1940		383,933	5,175,928	156,908,000	14,998,000	23,666,000

Custom mills were operated in various parts of Nevada during 1941; all used the cyanide process. Those of importance were at Silver City, Lyon County; Westgate, Churchill County; Gold Point, Esmeralda County; Adelaide, Humboldt County; and Kincaid, Mineral County. Most of the custom mills obtained part of their mill feed from mines controlled by the mill operators. Large quantities of ore and concentrates were shipped out of the State, principally to lead and copper smelters in the Salt Lake Basin. The

Bauer (Utah) plant of the Combined Metals Reduction Co. treated all the company zinc-lead ore mined at Pioche, Lincoln County, until September, when the new Pioche mill was put into operation; the Pioche mill treated ore from its neighbor, the Black Prince mine, upon a custom basis. The McGill copper smelter at McGill in White Pine County, operated by the Nevada Consolidated Copper Corporation, continued in 1941 to be the only smelter and the most important metallurgical plant in the State; the concentrator (daily capacity increased in 1941 from 18,000 to 20,000 tons), operated by the same company, was the largest mill in the State. The Consolidated Coppermines Corporation shipped its copper ore to the McGill concentrator for treatment.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Nevada in 1941, by types of mills and by counties, in terms of recovered metals

[1] Only those districts shown separately for which Bureau of Mines is at liberty to publish figures, other producing districts listed in footnote 8 and their output included under "Other districts."
[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[3] Source of total silver as follows: 5,816,205 ounces from lode mines and 14,033 ounces from placers
[4] Tonopah district lies in both Esmeralda and Nye Counties.
[5] Battle Mountain district lies in both Humboldt and Lander Counties.
[6] Central and Sawtooth districts lie in both Humboldt and Pershing Counties.
[7] Output from property not classed as a "mine."
[8] Includes following districts. Potosi in Humboldt County, Lewis in Lander County; Talapoosa in Lyon County; Echo in Pershing County; and Kinsley in White Pine County.

CHURCHILL COUNTY

The Westgate Mining & Milling Corporation, operator of a custom cyanide mill at Westgate, was reorganized in 1941 as the Silver State Milling Corporation. This plant treated 9,170 tons of ore from 40 shippers and continued to be an important factor in the mining industry of Churchill County.

Dixie Valley district.—The Comstock-Keystone Mining Co. operated the Dixie mine from January 1 to March 31, 1941, when it was leased to Dale & Hargrove who continued operations until the end of the year. A total of 2,731 tons of ore was treated in a 20-ton amalgamation mill, followed by table concentration and cyanide leaching of the sands; the amalgamation bullion contained 1,050 ounces of gold and 865 ounces of silver, cyanidation precipitates contained 439 ounces of gold and 621 ounces of silver, and 14 tons of concentrates shipped to a smelter contained 121 ounces of gold and 309 ounces of silver. In addition, 1 ton (1,767 pounds) of high-grade ore shipped to a smelter yielded 204 ounces of gold and 384 ounces of silver.

Eastgate district.—Schweiss & Luce shipped gold ore from the Gold Ledge mine to a custom cyanide mill in 1941.

Fairview district.—Several groups of lessees worked the Nevada Hills mine and produced 4,029 tons of gold-silver ore; 3,953 tons shipped to custom cyanide plants yielded 531 ounces of gold and 42,957 ounces of silver, and 76 tons of ore shipped to a smelter contained 50 ounces of gold, 3,253 ounces of silver, and 130 pounds of copper.

Holy Cross district.—Several groups of lessees on the Pyramid group shipped ore to a custom cyanide mill in 1941.

Sand Springs district.—Summit King Mines, Ltd., operated the Dan Tucker mine throughout 1941 and treated the ore in the company 65-ton all-slime cyanide plant. The Dan Tucker Extension Mining Co. shipped 155 tons of ore, yielding 13 ounces of gold and 4,212 ounces of silver, from the Double Ender mine to a custom cyanide mill; operations were suspended, and the lease was relinquished during the year.

Wonder district.—Lessees shipped gold-silver ore from the Giger mine to custom cyanide mills during 1941. Lessees operated the Jack Pot and Grand View mines. Several groups of lessees worked the Nevada Wonder mine. A. W. Schulze shipped silver ore from the Queen-Vulture mine to a custom cyanide mill.

CLARK COUNTY

Eldorado Canyon district.—The El Dorado-Rover Mining Co. operated the Quaker City, Magnolia, Crown, and Nevada Eagle groups of claims throughout 1941. Gold-silver ore was shipped to a smelter from the Occidental mine. Silver ore shipped to a smelter from the Oro Plata (Belmont Phoenix) mine contained 66 ounces of gold, 16,243 ounces of silver, 217 pounds of copper, and 901 pounds of lead. The Diamond Gold Mining Co. operated the Techatticup, Jubilee, and Red Butte mines throughout 1941; the ore was treated in a 100-ton flotation mill during the early months of the year but after July in a new 200-ton cyanide mill. W. W. Hartman operated the Wall Street mine.

Searchlight district.—Lessees operated the Blossom mine during 1941. H. H. Lang worked the Good Hope mine. W. H. Kelsey operated the M & M property. The Monte Carlo group was active. F. P. Jackson shipped ore from the Valley mine to a custom mill and a smelter.

Yellow Pine (Goodsprings) district.—H. V. Jarman shipped lead and zinc-lead ores from the Addison mine in 1941. The Chiquita Mining Co., Ltd., operated the Chiquita mine. O. F. Schwartz (Barefoot Lease) operated the Golden Chariot mine; 367 tons of ore treated by amalgamation yielded 27 ounces of gold and 4 ounces of silver, and 10 tons of flotation concentrates shipped to a smelter contained 23 ounces of gold, 1 ounce of silver, and 170 pounds of copper; in addition, 36 tons of ore containing 83 ounces of gold, 12 ounces of silver, and 692 pounds of copper were shipped to a smelter. O. F. Schwartz also operated the Hoosier and Keystone-Barefoot mines. F. Williams shipped 57 tons of zinc ore containing 4,053 pounds of lead and 33,618 pounds of zinc from the Hoodoo Nos. 1 and 2. Gressman & Flukey shipped 60 tons of zinc ore containing 7,794 pounds of lead and 32,358 pounds of zinc from the Milford No. 1 mine. From the Milford No. 2 T. J. Hammons and R. H. Reed shipped 8 tons of lead ore, containing 35 ounces of silver and 11,507 pounds of lead, and 179 tons of zinc-lead ore, containing 59,262 pounds of lead and 100,961 pounds of zinc. Jacobson, Krider, and Reim, lessees on the Sultan mine, shipped 414 tons of lead ore to a custom flotation mill and 61 tons of zinc ore to a smelter; the 60 tons of resulting concentrates contained 1 ounce of gold, 2,163 ounces of silver, 119 pounds of copper, and 61,378 pounds of lead, and the 61 tons of zinc ore contained 4,929 pounds of lead and 51,469 pounds of zinc. From the Tam O'Shanter mine Jacobson and Krider shipped to a smelter 266 tons of lead ore containing 1,736 ounces of silver, 205 pounds of copper, and 41,776 pounds of lead. The Yellow Pine Lease operated the Yellow Pine mine throughout 1941 and shipped zinc ore to a smelter.

ELKO COUNTY

Cope (Mountain City) district.—The Mountain City Copper Co. (third-largest copper producer in Nevada) was active throughout 1941; part of the ore was treated in the company 400-ton flotation mill, and high-grade ore was shipped for direct smelting. The Morrison-Knudsen Co., Inc., operated a dragline dredge, using a dragline excavator with a 2-cubic yard bucket, at the Van Duzer mine on Van Duzer Creek from April 1 to December 20.

Delano district.—Lessees on the Cleveland mine shipped 233 tons of lead ore containing 2 ounces of gold, 6,377 ounces of silver, 1,759 pounds of copper, and 87,909 pounds of lead during 1941. Lessees on the Net Group shipped to a smelter 1,145 tons of lead ore containing 8 ounces of gold, 21,915 ounces of silver, 6,889 pounds of copper, and 361,418 pounds of lead.

Dolly Varden district.—E. G. Gibson shipped copper ore from the Victoria mine to a smelter in 1941.

Gold Circle district.—Gold & Silver Circle Mines, Inc., was the largest producer of gold and silver in the district in 1941. Esmeralda Gold Mines, Ltd., operated the Esmeralda mine and treated gold ore by cyanidation. W. Collins worked the Miner's Gold mine.

Lime Mountain district.—Lime Mountain Consolidated operated the Lime Mountain mine throughout 1941; 2,960 tons of ore shipped to a smelter contained 1,247 ounces of gold, 3,375 ounces of silver, and 72,880 pounds of copper.

Mardis district.—From the Virginia mine in 1941 J. M. Prunty shipped to a smelter 62 tons of ore containing 186 ounces of gold, 121 ounces of silver, and 700 pounds of copper.

Merrimac (Lone Mountain) district.—The Rip Van Winkle Consolidated Mining Co. treated 7,376 tons of zinc-lead ore in the company 100-ton flotation mill and shipped to a smelter 691 tons of lead concentrates (containing 13 ounces of gold, 88,295 ounces of silver, 13,519 pounds of copper, and 883,312 pounds of lead) and 554 tons of zinc concentrates (containing 3 ounces of gold, 2,827 ounces of silver, 5,745 pounds of copper, 5,760 pounds of lead, and 539,779 pounds of zinc).

Spruce Mountain (Black Forest) district.—The Missouri Monarch Consolidated Mines Co. operated the Missouri Monarch mine from January 1 to October 31, 1941, when the property was leased to L. M. Conley who continued operations until the end of the year; silver ore, copper ore, and lead ore were shipped to a smelter.

ESMERALDA COUNTY

Divide district.—Several groups of lessees on the Tonopah Divide mine shipped 632 tons of gold ore containing 376 ounces of gold and 5,887 ounces of silver to a smelter during 1941.

Goldfield district.—The Diamondfield Daisy Gold Mining Co. shipped gold ore from the Diamond Daisy mine to a smelter in 1941. Several groups of lessees worked the Black Butte, Florence, and Merger claims of the Goldfield Deep Mines Co. of Nevada. The Goldfield Consolidated Mines Co. property was operated by several groups of lessees.

Hornsilver (Gold Point) district.—The Ohio Mines Corporation operated the Ohio group throughout 1941; in addition to company ore, over 2,400 tons of custom material received from 37 shippers was treated in the company 50-ton cyanide mill. The Orleans mine, one of the Ohio group, was operated as the Midnight Lease. Several groups of lessees on the Tokop mine shipped ore to a custom cyanide mill.

Klondyke district.—The Original Klondyke Divide Mining Co. shipped lead ore from the Original Klondyke mine to a smelter in 1941.

Oneota district.—The Red Top Mining Co. constructed a cyanide mill at the Brownie mine in 1941, which was operated for a short period during the year.

Silver Peak district.—In 1941 Desert Silver, Inc., worked the Nivloc mine, leading silver producer in the State since 1938. The Silver Divide Mines Co. operated the Coyette mine from August to December 1941. E. L. Cord, operating as the Prescott Lease, worked the Mary mine throughout the year; ore was treated in the company 350-ton flotation-amalgamation-cyanide mill. Lessees shipped gold ore from the Oromonte mine to a custom cyanide mill and to a smelter. The Silver Peak Custom Milling Co. operated the Black Mammoth mill as a custom plant for a short period in 1941 before it was destroyed by fire September 23.

EUREKA COUNTY

Buckhorn district.—Between March 1 and December 15, 1941, D. P. Murphy shipped ore from the Buckhorn mine dumps to a smelter.

Cortez district.—Lessees shipped silver ore from the Cortez mine to a smelter during 1941. The Ventura mine was active throughout the year; 864 tons of ore containing 760 ounces of gold, 623 ounces of silver, and 524 pounds of copper were shipped to a smelter.

Eureka district.—A lessee operated the Colorado mine and shipped gold ore to a smelter in 1941. The Eureka Prospect Co. worked the Diamond Excelsior mine intermittently. Lessees worked the Eureka Croesus mine. The Eureka Corporation, Ltd., shipped ore from several properties in the Eureka district; the largest production came from the Oswego property in the Secret Canyon section.

HUMBOLDT COUNTY

Awakening (Slumbering Hills) district.—Austin Bros. Gold Mining Co. operated the Jumbo group from May 11 to October 18, 1941.

Barrett Springs (Ten-mile) district.—West Coast Mines, Inc., began operation of its new 150-ton flotation mill at the Pansy Lee mine February 1, 1941; 39,598 tons of ore milled yielded 7,882 tons of concentrates containing 5,314 ounces of gold, 453,508 ounces of silver, 71,130 pounds of copper, and 1,018,842 pounds of lead; and 407 tons of ore shipped to a smelter contained 157 ounces of gold, 13,217 ounces of silver, 2,929 pounds of copper, and 30,894 pounds of lead. This mine was the third-largest producer of silver in the State in 1941. King Gold Mines in the Ten-mile section of the Barrett Springs district was active during 1941.

Battle Mountain district.—The B. & M. Mining Co. operated a nonfloating washing plant at the Johnny Boy placer group from June 12 to November 24, 1941. Gravel was delivered to the plant by a dragline excavator using a 1½-cubic yard bucket.

Gold Run (Adelaide) district.—Adelaide Crown Mines operated the Adelaide Crown mine throughout 1941; 96,898 tons of ore treated in the company 300-ton all-slime cyanide mill yielded 5,249 ounces of gold and 113,705 ounces of silver; the company also treated 2,287 tons of custom ore from 18 shippers. Marigold Mines, Inc., worked the Marigold mine and shipped ore to custom cyanide mills and to a smelter.

National district.—A lessee operated the Buckskin mine from April 1 to December 31, 1941; 639 tons of ore shipped to custom cyanide mills contained 453 ounces of gold and 2,210 ounces of silver, and 103 tons of ore shipped to a smelter contained 110 ounces of gold, 589 ounces of silver, 94 pounds of copper, and 157 pounds of lead. Lessees mined 2 tons of very high grade ore at the National mine; in August the mine was leased to the Santa Rosa Mining Co., subject to the leases already in effect.

Potosi district.—Getchell Mine, Inc., operated the Getchell mine throughout 1941 and continued to hold first place in Nevada as a gold producer. Ore was treated in the company 1,000-ton cyanide plant, to which a 260- by 7½-foot rotary kiln was added during the year.

497779—43——28

Warm Springs district.—Gold ore was treated by amalgamation at the Ashdown mine in 1941. The Homer Verne Mining Co. operated the Homer Verne mine in the Boyd Basin section of the Warm Springs district.

LANDER COUNTY

Battle Mountain district.—In 1941, as in former years, lessees at the various small mines in the Battle Mountain district produced much of the ore shipped to smelters. Small mines that were active included the Armour, Bentley, Big Florence, Buffalo Valley, Buzzard, Copper Queen, Eldorado, Gold Butte, Gold Cash, Gold Road, Hard Times, Oriole, Plumas, San Miguel, Trinity, and White. The International Smelting & Refining Co. took a 5-year lease on the property of the Copper Canyon Mining Co. with option to purchase 51 percent of the Copper Canyon Mining Co. stock. The lessee budgeted $500,000 for examination and the construction of a 350-ton flotation mill, building of which was started late in the year. In addition to examination and construction activities, a substantial quantity of copper ore was shipped to a smelter during 1941. Broyles and Wilson, one of the larger lessees in the district, shipped gold-silver ore from the Independence group.

Bullion district.—H. W. Treweek operated a cyanide mill on the Goldacres property during 1941. The Gray Eagle Mining Co. worked the Gray Eagle mine. Lessees operated the Little Gem mine and treated silver ore by flotation; copper ore was shipped to a smelter. Several operators on Triplett Gulch produced 413 ounces of gold and 40 ounces of silver from placer gravels.

McCoy district.—The Nevada United Gold Mining Co. cyanided a substantial quantity of gold ore produced at the Gold Dome mine during 1941.

New Pass district.—New Pass Mines operated the New Pass mine from January 1 to December 22, 1941. W. H. Smith treated 291 tons of ore from the Thomas W. mine and recovered 146 ounces of gold and 23 ounces of silver.

LINCOLN COUNTY

Comet district.—The Comet Mines Co. carried on test runs at the Comet mine during 1941; 565 tons of ore were treated by flotation, and 7 tons of resulting concentrates shipped to a smelter contained 17 ounces of gold, 665 ounces of silver, 90 pounds of copper, and 656 pounds of lead; and 346 tons of ore shipped to a smelter contained 81 ounces of gold, 2,845 ounces of silver, 404 pounds of copper, and 13,405 pounds of lead.

Ferguson (Delamar) district.—During 1941 lessees shipped gold ore to a smelter from the properties owned by the Delamar Exploration Co.

Jack Rabbit (Bristol) district.—The Bristol Silver Mines Co. operated the Bristol Silver mine throughout 1941; 18,576 tons of lead ore containing 178 ounces of gold, 305,232 ounces of silver, 1,002,198 pounds of copper, and 1,975,935 pounds of lead were shipped to a smelter.

Pioche district.—The Combined Metals Reduction Co. (affiliate of the National Lead Co.) worked the Pioche Nos. 1 and 2 mines and a section of the Amalgamated Pioche mine throughout 1941; the company was the largest producer of both lead and zinc in the State.

From January until September all the production was shipped to the company 600-ton selective-flotation mill at Bauer, Utah, but from September until the end of the year virtually all the output was treated in the 600-ton selective-flotation mill erected by the company at Castleton 3 miles southwest of Pioche. In addition to company ore, this new mill handled ore from the Black Prince mine for the Prince Consolidated Mining Co. The Amalgamated Pioche Mines & Smelters Corporation shipped lead ore from a section of the Amalgamated Pioche mine to a smelter in 1941. W. A. Free shipped lead ore from the Apex and the Financier mines to a smelter. The Nevada Volcano Mines Co. operated the Nevada Volcano mine from May 29 to December 31 and shipped lead ore to a smelter. The Hall Bros. Co., Inc., shipped from the Raymond Ely mine to a smelter 27,006 tons of gold-silver ore containing 1,217 ounces of gold and 130,700 ounces of silver. Lessees shipped gold-silver smelting ore from the Wide Awake mine.

LYON COUNTY

Palmyra district.—T. Panos shipped gold ore from the Carpenter mine to a custom cyanide mill. P. Haggerty, a lessee on the Hulley Logan mine, shipped gold-silver ore to a custom cyanide mill. A. Lundgren shipped gold-silver ore from the North Rapidan mine to a custom cyanide mill.

Pine Grove (Wilson) district.—G. L. Felt, a lessee, operated the Wilson mine from February 1 until December 31, 1941, and reconstructed the mill at the property as a 150-ton flotation plant; gold concentrates were shipped to a custom cyanide mill and to a smelter.

Silver City district.—The Dayton Consolidated Mines Co. operated the Dayton mine in 1941 on company account and through lessees. In addition to the Dayton mine ore, the company treated ore it mined at other properties in the Silver City district and more than 20,000 tons of custom ore received from 250 shippers working mines in Silver City and other districts. Gold ore from the Haywood mine was shipped to the Dayton mill. The Gold Rock Mining Co. and lessees operated the Buckeye group; the company reconstructed the mill as a 75-ton amalgamation-flotation plant. A number of lessees working the Oest mine produced 863 tons of ore, from which 284 ounces of gold and 479 ounces of silver were recovered; some of the ore was amalgamated and some shipped to a custom cyanide mill. Lessees operated the Silver City mine. The Dayton Dredging Co. operated a dragline dredge at its property on the north edge of Dayton from January 1 to December 31; the dragline dredge used a dragline excavator with a 14-cubic yard bucket which, when installed, was the largest used in dragline dredging in the world.

Talapoosa district.—F. J. de Longchamps operated the Talapoosa mine from January to July 1941 and shipped ore to the Dayton Consolidated Mining Co. custom mill for treatment.

MINERAL COUNTY

Columbus (Candelaria) district.—Gold-silver ore from the Silver King mine was shipped to a smelter in 1941.

Hawthorne (Pamlico, Ashby) district.—Lessees on the Ashby mine shipped gold ore to custom cyanide mills during 1941. Champion

City Mines, Inc., treated 1,326 tons of silver ore in the company 200-ton flotation mill and shipped to a smelter 88 tons of lead concentrates containing 3 ounces of gold, 27,796 ounces of silver, 3,012 pounds of copper, and 75,020 pounds of lead.

Santa Fe district.—Lessees shipped gold ore from the Clay Peters group to a smelter in 1941.

Silver Star (Gold Range) district.—Lessees on the Lancashire mine shipped gold-silver ore to a custom cyanide mill and lead ore to a smelter in 1941.

NYE COUNTY

Bellehelen district.—Western Gold, Inc., shipped gold-silver ore from the dumps of the Clifford mine to a smelter during 1941.

Belmont district.—Ore and old tailings, valued chiefly for silver, were shipped to a smelter from the Combination mine in 1941.

Bullfrog district.—C. L. Tibbols operated the Denver mine from January 8 to September 2, 1941; 257 tons of ore shipped to custom cyanide mills yielded 149 ounces of gold and 202 ounces of silver. M. F. Hazen operated the May Flower mine from February to November. Lessees operated the Senator Stewart mine from January 11 to March 11.

Golden Arrow district.—Gold-silver ore from the Golden Arrow mine was shipped to a smelter in 1941. Lessees on the Golden Bar mine shipped gold ore to a custom mill and to a smelter.

Manhattan district.—Lessees on the April Fool mine in 1941 produced 328 tons of ore from which 240 ounces of gold and 89 ounces of silver were recovered by amalgamation and cyanidation. The Big Four mine was operated by lessees. J. Francisco operated the Jumbo mine under lease from January to November and treated gold ore in his 35-ton stamp mill located on a nearby property. Lessees worked the Manhattan mine and treated gold ore in a 5-stamp amalgamation mill. Lessees worked the Nevada Coalition mine. The Reliance Mining Co. suspended operations at the Verden mine in June 1941; during the year, a substantial quantity of gold was recovered from clean-up of the mill and high-grade ore shipped to a smelter. The Manhattan Gold Dredging Co. (largest producer of placer gold in the State since 1939) operated throughout 1941 its electric connected-bucket dredge equipped with 108 9½-cubic foot buckets.

Northumberland district.—The Northumberland Mining Co. operated the Northumberland mine throughout 1941.

Phonolite district.—A clean-up at the Penelas mine in 1941 yielded a substantial quantity of gold and silver.

Quartz Mountain district.—O. LeFavor shipped lead ore from the San Rafael mine to a smelter in 1941.

Round Mountain district.—Morrin & Steigmeyer operated the Gold Hill mine during 1941. S. W. Boswick worked for 40 days the Mary McLean mine in the Red Mountain section of the Round Mountain district. J. J. Raymond worked the Monte Christo mine.

Silver Bow district.—In 1941 silver ore from the Catlin and Hillside mines was shipped to a smelter. In addition, some gold-silver ore from the Hillside mine was treated in a custom cyanide mill.

Tonopah district.—Gold-silver ore mined by a lessee at the Jim Butler mine was shipped to a smelter in 1941. Lessees shipped 446 tons of gold-silver ore containing 207 ounces of gold and 18,937 ounces of silver from the Tonopah Belmont mine. Silver ore and mill clean-

up from the Tonopah Extension mine were shipped to a smelter. Several sets of lessees operated the Tonopah Mining Co. of Nevada property throughout 1941 and shipped gold-silver ore to a smelter. Lessees on the West End mine shipped silver ore to a smelter.

Tybo district.—Silver ore from the Ramona mine was shipped to a smelter during 1941. Lessees shipped to a smelter gold-silver ore and lead ore from the Two G mine.

Union district.—Silver Palace Mines, Inc., operated the Silver Palace mine from April until the end of 1941, and 12,233 tons of silver ore were treated in a 50-ton flotation plant built during the year; 613 tons of lead concentrates recovered contained 3 ounces of gold, 85,283 ounces of silver, 12,443 pounds of copper, 230,202 pounds of lead, and 188,411 pounds of zinc. The company planned adding selective flotation to produce a zinc concentrate.

PERSHING COUNTY

Central district.—Jones Bros. & Associates worked the Keystone mine in 1941; 501 tons of lead ore shipped to a smelter contained 21 ounces of gold, 18,904 ounces of silver, 1,924 pounds of copper, and 68,313 pounds of lead.

Imlay district.—The Standard Cyaniding Co. operated the Gold Standard mine throughout 1941. Between April 15 and December 20 J. K. Wadley treated in a 4-ton amalgamation mill 27 tons of ore from a property 20 miles west of Imlay and recovered 317 ounces of gold and 166 ounces of silver.

Rochester district.—E. McCartney shipped gold-silver ore from the West Slope mine to a custom cyanide mill.

Rosebud district.—P. Webster operated the Brown Palace mine from January 1 to October 1, 1941, and treated the ore in a 20-ton cyanide plant. Acme Gold Placers, Inc., operated a nonfloating washing plant on the Acme property.

Seven Troughs district.—Laughton & Causten operated the Portland mine throughout 1941; ore was treated in a 25-ton amalgamation-concentration mill.

Staggs district.—The Twin Buttes Mining Syndicate operated the Twin Buttes mine throughout 1941; 524 tons of ore shipped to a smelter contained 530 ounces of gold, 6,151 ounces of silver, 54 pounds of copper, and 40,573 pounds of lead.

STOREY COUNTY

Comstock district.—Lessees on the Chollar-Potosi mine in 1941 shipped to a custom cyanide mill 1,041 tons of ore from which 370 ounces of gold and 8,476 ounces of silver were recovered. The Consolidated Virginia Mining Co. operated the Consolidated Virginia mine continuously. Sutro Tunnel Coalition, Inc., operated the Crown Point mine throughout the year; the output of gold-silver ore was treated in the company 100-ton cyanide mill. The Dayton Consolidated Mines Co. and lessees shipped 2,131 tons of ore to the Dayton Consolidated cyanide mill in Silver City; 606 ounces of gold and 8,286 ounces of silver were recovered. This company and lessees worked the Keystone mine and produced 28,697 tons of ore from which 8,167 ounces of gold and 22,554 ounces of silver were recovered by cyanidation. The Dayton Consolidated Mines Co. operated the

New York mine throughout the year. Lessees shipped 873 tons of ore from the Occidental mine to a custom cyanide mill; 176 ounces of gold and 5,848 ounces of silver were recovered. The Nevada Securities Co. worked the Overland mine. The Consolidated Chollar Gould & Savage Mining Co. operated the Overman mine continuously. The Silver Hill Mining Co. operated the Silver Hill and Succor mines and treated the ore in the company 100-ton amalgamation-cyanidation mill. Sierra Nevada, Ltd., and lessees worked the Sierra Nevada mine.

WASHOE COUNTY

White Horse district.—The Renegade mine was operated during 1941; 361 tons of ore treated by amalgamation yielded 284 ounces of gold and 88 ounces of silver, and 149 tons of ore shipped to a custom cyanide mill yielded 402 ounces of gold and 116 ounces of silver.

WHITE PINE COUNTY

Aurum district.—The Grand Deposit Mining Co. and lessees worked the Grand Deposit mine during 1941; copper ore and lead ore were shipped to a smelter and zinc ore to a zinc oxide plant for treatment.

Cherry Creek district.—Several groups of leasers on the Eagen mine in 1941 shipped to a smelter 1,656 tons of ore and 949 tons of old tailings, containing in all 461 ounces of gold and 10,502 ounces of silver. The Exchequer Mining Co. shipped silver ore from the Imperial mine to a smelter. The Nevada Standard Mining Co. and lessees shipped gold-silver ore and silver ore from the Star mine. Old tailings were shipped from the Thompson tailing pile to a smelter.

Robinson district.—The Nevada Consolidated Copper Corporation (operating subsidiary of the Kennecott Copper Corporation and largest industrial company in Nevada) operated the Ruth mine at Ruth and the open pit at Copper Flat throughout 1941. In addition to its mining activities, the company operated the McGill copper smelter (only smelter in the State) and the McGill flotation-concentrator, which was increased in 1941 from 18,000- to 20,000-ton daily capacity The Consolidated Coppermines Corporation, second-largest copper producer in the State in 1941, was active throughout the year; copper ore mined on company account was shipped to the McGill concentrator. C. Caviglia shipped from the Chainman mine to a smelter 4,517 tons of ore containing 654 ounces of gold and 5,785 ounces of silver. The Ely Gold & Manganese Co. and lessees operated the Cuba mine The Hayes mine was operated by D. F. Paine until May; operations were continued by the D. F. Paine estate. During August and September lessees shipped 598 tons of gold-silver ore, containing 113 ounces of gold, 3,145 ounces of silver, and 942 pounds of copper, from the Hidden Treasure mine to a smelter. L. Piombo operated the Jupiter Lease and shipped gold-silver ore to a smelter. L. Burnham worked the Keystone mine from March to September. The Ely Gold Mining Co. shipped gold-silver ore from the Revenue mine.

Taylor district.—Lessees shipped silver ore from the Gore mine during 1941. Farnsworth-Ely Combined Metals Mines shipped silver ore from the Mineral Farm mine to a smelter during the first 4 months of the year. Lessees worked the Monitor and Sunrise mines.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEW MEXICO

(MINE REPORT)

By Chas. W. Henderson and A. J. Martin

SUMMARY OUTLINE

SUMMARY

Production of both copper and zinc in New Mexico in 1941 was larger in quantity than in any previous year, and that of lead was greater than in 1940 but less than in 1939. The output of both gold

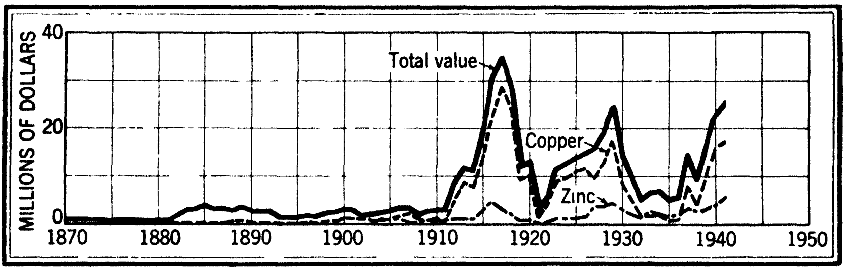

Figure 1.—Value of mine production of copper and zinc and total value of gold, silver, copper, lead, and zinc in New Mexico, 1870–1941. The value of gold, silver, and lead produced annually has been relatively small.

and silver decreased. The total value of the recovered output of the five metals in 1941 was $25,471,416 (highest since 1918) and compares with $22,246,421 in 1940 (see fig. 1). Copper represented 68 percent and zinc 22 percent of the total value in 1941; the zinc value was the highest in any year on record for the State, and the copper value was the largest since 1918. All the principal producing mines and mills that were active in 1940 continued operations throughout 1941, with the exception of the Aztec mine and 140-ton amalgamation-flotation mill in Colfax County and the San Pedro group and 150-ton flotation mill in Santa Fe County (shut down in August). The Waldo mine and 200-ton flotation mill near Magdalena were reopened and began producing in September.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4].646+	.098	.046	.048
1939	35.00	[5].678+	.104	.047	.052
1940	35.00	[6].711+	.113	.050	.063
1941	35.00	[6].711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20 67+($20.671835) per fine ounce.
[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938–41: Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

The following table shows the number of mines in New Mexico producing gold, silver, copper, lead, and zinc and their annual output of ore and metals from 1937 to 1941; also the total production from 1848 to 1941. The report of this series for 1929 (chapter of Mineral Resources of the United States, 1929, pt. 1, pp. 729–759) gives the yearly production of each important metal-producing district in New Mexico from 1904 to 1929, inclusive. Subsequent records year by year may be found in annual issues of Mineral Resources and Minerals Yearbook.

Mine production of gold, silver, copper, lead, and zinc in New Mexico, 1937–41, and total, 1848–1941, in terms of recovered metals

Year	Mines producing: Lode	Mines producing: Placer	Ore (short tons)	Gold (lode and placer): Fine ounces	Gold (lode and placer): Value	Silver (lode and placer): Fine ounces	Silver (lode and placer): Value
1937	159	160	4,191,092	41,171	$1,440,985	1,243,766	$962,053
1938	166	164	2,414,857	43,050	1,506,750	1,229,860	795,061
1939	214	168	4,977,375	36,979	1,294,265	1,400,878	950,899
1940	164	179	7,089,903	35,943	1,258,005	1,407,839	1,001,130
1941	145	103	7,530,226	27,845	974,575	1,328,317	944,581
1848–1941			(1)	2,148,780	48,541,493	65,276,576	51,150,206

Year	Copper: Pounds	Copper: Value	Lead: Pounds	Lead: Value	Zinc: Pounds	Zinc: Value	Total value
1937	64,106,000	$7,756,826	13,024,000	$768,416	47,854,000	$3,110,510	$14,038,790
1938	40,878,000	4,006,044	9,898,000	455,308	56,472,000	2,710,656	9,473,819
1939	92,284,000	9,597,536	10,784,000	506,848	58,712,000	3,053,024	15,402,572

Gold and silver produced at placer mines in New Mexico, 1937–41, in terms of recovered metals

Year	Gold: Fine ounces	Gold: Value	Silver: Fine ounces	Silver: Value	Total value	Year	Gold: Fine ounces	Gold: Value	Silver: Fine ounces	Silver: Value	Total value
1937	3,027	$105,945	203	$157	$106,102	1940	2,928	$102,480	263	$187	$102,667
1938	2,626	91,910	167	108	92,018	1941	2,488	87,080	284	202	87,282
1939	3,474	121,590	209	142	121,732						

Gold.—Mine production of gold in New Mexico decreased from 35,943 fine ounces in 1940 to 27,845 ounces in 1941. Changes in output in the principal gold-producing districts in 1941 were: Decreases of 1,877 ounces in the Mogollon district, 570 ounces in the Mount Baldy, 951 ounces in the Hillsboro, 1,737 ounces in the Central, 955 ounces in the Lordsburg, 1,641 ounces in the San Pedro, and 359 ounces in the Pinos Altos district; output increased 1,271 ounces in the Steeple Rock district. Dry and siliceous ores yielded 57 percent of the State total gold, copper ore 32 percent, lead and zinc-lead ores 2 percent, and placers 9 percent.

Silver.—Mine production of silver in New Mexico was 1,328,317 fine ounces in 1941 compared with 1,407,839 ounces in 1940. The Mogollon district contributed 37 percent of the State total in 1941, Central 36 percent, Steeple Rock 19 percent, Lordsburg 5 percent, and San Pedro 1 percent. Dry and siliceous ores yielded 57 percent of the total silver; copper ore 18 percent; zinc-lead ore 24 percent; and lead ore, together with a small quantity of silver from placers, 1 percent.

Copper.—The output of recoverable copper from mines in New Mexico in 1941 was 146,956,000 pounds—a 5-percent increase over the former record annual production (in 1940). The Chino open-pit mine of the Nevada Consolidated Copper Corporation at Santa Rita, Grant County, continued to be much the largest producer in the State. The daily capacity of the concentrator at Hurley was 20,000 tons at the end of 1941. The copper concentrates are reduced to blister copper in the smelter adjacent to the concentrator. Molybdenite concentrates are recovered in the mill as a byproduct. Other sizable producers of copper were the Burro Mountain group of the Phelps Dodge Corporation at Tyrone, Grant County; the Bonney mine near Lordsburg, Hidalgo County; the San Pedro near Golden, Santa Fe County (operated January to August); and the Ground Hog-San Jose group near Hanover, Grant County. Copper ore and mine-water precipitates yielded 98 percent of the total copper; most of the remainder was recovered from concentrates produced from the milling of zinc-lead ore.

Lead.—The bulk of the lead produced from New Mexico mines in 1941 came from the American Smelting & Refining Co. Ground Hog unit in the Central district, Grant County. The total State output of lead (9,336,000 pounds) was 22 percent above that in 1940. Zinc-lead ore yielded 88 percent of the total lead, lead ore 5 percent, copper ore 5 percent, and other types of ore 2 percent.

Zinc.—The output of recoverable zinc from mines in New Mexico increased 25 percent in 1941 over 1940. The principal producers in 1941 were the American Smelting & Refining Co. (Ground Hog unit), Empire Zinc Co. (Hanover mine group), and the Peru Mining Co. (Pewabic mine), all in the Central district, Grant County; and Raskob Mining Interests, Inc. (Waldo mine operation) and the Empire Zinc Co. (Kelly group), both in the Magdalena district, Socorro County. Other districts producing some zinc were the Organ, Dona Ana County; Pinos Altos and Swartz, Grant County; and Lordsburg and San Simon, Hidalgo County.

Zinc concentrates produced in 1941 amounted to 80,774 tons, containing as shipped 20 ounces of gold, 56,215 ounces of silver, 603,467 pounds of copper, 1,117,017 pounds of lead, and 87,362,425 pounds of zinc. The average content in zinc was therefore 54.08

percent. The zinc and zinc-lead ores (1,492 tons) from New Mexico shipped crude to the Ozark pigment plant at Coffeyville, Kans., averaged 22.86 percent zinc and 12.40 percent lead.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in New Mexico in 1941, by counties, in terms of recovered metals

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)

[1] Dragline and power-shovel excavators with sluices or special amalgamators.

MINING INDUSTRY

The greater part of the 7,530,226 tons of ore produced in New Mexico in 1941 was copper ore, mined with power shovels, from the Chino open-pit mine at Santa Rita, Grant County. Underground mining was done at the other principal mines of the State. The quantity of each type of ore produced, with its content in terms of recovered metals, is shown in the table that follows. Operating details at both lode and placer mines are given in the following review by counties and districts.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in New Mexico in 1941, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	18,305	4,360	18,036	66,414	225,555	
Dry and siliceous gold-silver ore	89,430	11,598	728,462	7,267	2,206	
Dry and siliceous silver ore	282	8	7,732	899	6,494	
	108,017	15,966	754,230	74,580	234,255	
Copper ore	6,975,682	8,908	242,834	[1] 144,714,904	429,254	
Lead ore	2,261	423	7,200	9,827	450,987	
Zinc ore	148,359				382	26,586,093
Zinc-lead ore	295,907	60	323,769	2,156,689	8,221,122	49,137,907
	7,422,209	9,391	573,803	[1] 146,881,420	9,101,745	75,724,000
Total, lode mines	7,530,226	25,357	1,328,033	[1] 146,956,000	9,336,000	75,724,000
Total, placers		2,488	284			
	7,530,226	27,845	1,328,317	[1] 146,956,000	9,336,000	75,724,000
Total, 1940	7,089,903	35,943	1,407,839	[2] 139,696,000	7,644,000	60,626,000

[1] Includes 16,818,294 pounds of copper recovered from mine-water precipitates.
[2] Includes 8,258,984 pounds of copper recovered from mine-water precipitates.

METALLURGIC INDUSTRY

The following eight flotation mills treated 98 percent of the total New Mexico output of ore in 1941: Chino at Hurley, Empire Zinc at Hanover, Banner near Lordsburg, Peru near Deming, Combination near Hanover, San Pedro near Golden, Waldo near Magdalena, and Southwest Minerals near Duncan, Ariz. (operated on ore from the Carlisle group at Steeple Rock, N. Mex.). One percent was treated by the Little Fanney cyanidation mill at Mogollon, the East Camp cyanidation mill at Steeple Rock, and scattered small concentration and amalgamation mills; and 1 percent was shipped crude to smelters. The Chino reverberatory copper smelter of the Nevada Consolidated Copper Corporation at Hurley was operated throughout 1941 on company copper concentrates, siliceous copper ore, and copper precipitates recovered by leaching of waste dumps. Concentrates and ore produced by other operators in the State were shipped to smelters in other States, mentioned in the following review by counties and districts. About 300,250 cubic yards of gravel were treated at four placer mines using dry-land dredges, and some gravel for which figures are not obtainable was handled at small placers worked by hand methods.

Mine production of metals in New Mexico in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated	5,908	986	249			
Ore cyanided [1]	84,611	10,081	690,217			
Concentrates smelted	313,725	10,757	518,113	[2] 144,281,312	8,173,537	75,179,301
Ore smelted	86,757	3,533	119,454	2,674,688	1,162,463	544,699
Placer		2,488	284			
		27,845	1,328,317	146,956,000	9,336,000	75,724,000
Total, 1940		35,943	1,407,839	139,696,000	7,644,000	60,626,000

[1] Cyanide used was approximately 342,800 pounds of Aero Brand calcium cyanide (approximately 48 to 49 percent NaCN).
[2] Includes 16,818,294 pounds of copper recovered from smelting of mine-water precipitates.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in New Mexico in 1941, by counties, in terms of recovered metals

[1] District lies in both Grant and Hidalgo Counties

BERNALILLO COUNTY

F. S. Hofheims shipped 16 tons of silver-gold ore from the Little Daisy claim to the El Paso smelter in 1941.

CATRON COUNTY

Mogollon district.—The Black Hawk Consolidated Mines Co. continued in 1941 to operate the Consolidated group (comprising the Andrew Jackson Consolidated, Lexington Contention, and Lexington Gunboat claims on the Queen vein) and the Little Fanney cyanide mill, both under lease from the Lehigh Metals Co. Besides ore from the Consolidated group, the mill treated custom ore from the Little Fanney, Maude S, Champion, Last Chance, and Pacific groups. Company and custom ore treated totaled 61,460 tons, from which 7,720 fine ounces of gold and 484,827 fine ounces of silver were recovered in bullion shipped to the Denver Mint. Some of the ore produced at the Last Chance group and a few lots of ore from the Bearup and Ruby properties were shipped crude to the El Paso smelter and Hawley & Hawley (ore buyers) at Douglas, Ariz.

Wilcox district.—In 1941 the owner of the Little Dry claim shipped 2 tons of ore to the Ira L. Wright assay office at Silver City; the ore assayed 0.14 ounce of gold and 8.4 ounces of silver to the ton.

COLFAX COUNTY

Mount Baldy district (Baldy, Elizabethtown, Eagle Nest).—All the output of gold and silver from the Mount Baldy district in 1941 came from placer mines. Fullroe, Inc., worked the Lynch Homestead and Grouse Gulch placers about 8 months, using a caterpillar bulldozer, 1¼-cubic yard dragline, and portable screening and sluicing plant. The Peerless Mining Co. operated its portable four-bowl washing machine, 1¼-cubic yard gasoline shovel, and caterpillar bulldozer from April 12 to November 17 on placer ground on Ute Creek. Individuals recovered small lots of placer gold by sluicing near Elizabethtown. No activity in mining or development was reported at lode mines in the Mount Baldy district in 1941. The mills at the Aztec and French Henry mines were dismantled.

DONA ANA COUNTY

Organ district.—A car of zinc-lead ore cleaned up from dumps on the Rickardite property was shipped to the Ozark Smelting & Mining Co. at Coffeyville, Kans., in 1941. About 6 tons of lead-silver ore were shipped to the El Paso smelter from the Seale & Hoffer group of claims, and a little ore was shipped from a prospect on which assessment work was being done.

EDDY COUNTY

Orvan F. Ammann shipped 9 tons of copper-silver ore to the El Paso smelter from his claim northwest of Carlsbad.

GRANT COUNTY

Burro Mountain district (Tyrone).—In March 1941 the Phelps Dodge Corporation began preparing its Burro Mountain mine (idle since

1921) for leaching. Water lines, power lines, and pumps were installed, and a precipitation plant was built. Production of copper was begun May 22 and continued the rest of the year. A lessee at the Barrio claim, owned by the Standard Silver Lead Mining Co., shipped small lots of gold-silver ore to buyers at Silver City, N. Mex., and Douglas, Ariz. Dry washing on placer ground in the Burro Mountain district recovered a little gold.

Central district (Bayard, Fierro, Georgetown, Hanover, Santa Rita).—The Nevada Consolidated Copper Corporation Chino Mines Division, largest producer of copper in New Mexico, operated its open-pit mine at Santa Rita and flotation mill and reverberatory copper smelter at Hurley throughout 1941. The output of copper was larger than in 1940 and set a new annual record. Improvements made in the mill in 1941 raised its capacity from 17,500 to 20,000 tons daily. The copper concentrates carry a low content of gold and silver. Molybdenite concentrates are recovered in the mill as a byproduct. The material smelted in 1941 included, besides concentrates from the mill, a considerable tonnage of siliceous carbonate copper ore (used as a flux) and copper precipitates recovered from leaching operations. The Twenty-seventh Annual Report of the Kennecott Copper Corporation, dated March 10, 1942, contains the following paragraphs regarding operations at the Chino property during 1941:

A total of 94,889,612 tons of rock was mined and moved at the four properties in Utah, Nevada, Arizona, and New Mexico. Of this total 51,180,803 tons were overburden which went to the waste dumps and 43,708,809 tons were ore sent to the concentrators. The average assay of the ore was 1.04 percent copper and there was produced a total of 819,648,759 pounds of copper during the year. The average monthly production was thus slightly in excess of 34,000 tons—varying from about 32,000 tons in the earlier months to 36,000 tons in the latter part of the year.

Chino mines.—The full electrification of the open-pit mine at Santa Rita was completed with the purchase of additional electric locomotives to replace the last of the steam motive power. Other new mine equipment included one 5-yard electric shovel and 20 dump cars. Sixteen new houses and a theater were built at the mine townsite.

At the mill and smelter at Hurley—about 8 miles from Santa Rita—the installation of a 230-foot diameter Dorr thickening tank was started, and a new lime-burning plant was nearly completed at the year end. Four wells were drilled to augment the water supply developing an initial flow of 800 gallons per minute. This additional gallonage together with the water that will be saved through the Dorr thickener installation should provide a sufficient supply to treat present ore tonnages in seasons of normal rainfall. Eight houses and a teachers' dormitory were constructed at the Hurley townsite.

Zinc production in the Central district rose 17 percent over 1940. The Peru Mining Co. expanded mining operations at its Pewabic mine and shipped a materially increased tonnage of ore to the company 500-ton mill near Deming. Besides ore from the Pewabic mine, the mill handled some zinc tailings from the Cleveland mine near Pinos Altos. The concentrates produced were shipped to the retort plant at Dumas, Tex. The Empire Zinc Co. operated its Hanover mine group and selective-flotation mill continuously in 1941. Although the quantity of zinc concentrates produced from Hanover ore was less than in 1940, the decline from this source was partly offset by concentrates made from ore shipped to the mill from the company Kelly mine in the Magdalena district, Socorro County. Most of the zinc concentrates produced were shipped to the New Jersey Zinc Co. plant at Depue, Ill. (Mineral Point Zinc Division); the byproduct

lead-copper concentrates made were shipped to the El Paso smelter. Zinc concentrate production from the Combination (Black Hawk) mill, operated under lease by the American Smelting & Refining Co., was nearly double that in 1940, and lead concentrate production also increased. Most of the ore treated came from the company Ground Hog-San Jose group which produced, in addition to mill-grade zinc-lead-copper-silver ore, a substantial tonnage of copper-lead-silver-gold and lead-copper-silver ores shipped crude to the El Paso smelter. The zinc concentrates produced were shipped to the Amarillo (Tex.) smelter and the lead-copper concentrates to El Paso. The mill handled considerable custom ore from the Combination and Hobo mines of the Black Hawk Consolidated Mines Co. and smaller quantities from the Bullfrog mine in the Central district, the Grandview in the Swartz (Carpenter) district, the Silver Hill near Pinos Altos, and the Ruth near Lordsburg. A few cars of ore were shipped to smelters from the Hanover Bessemer Iron & Copper Co. group, Lead King mine, and other properties in the Central district.

Chloride Flat district.—Small lots of lead-silver ore from the Hot Spot and Silver Queen claims and copper-silver ore from the Silver Monument were sold to Ira L. Wright, assayer and ore buyer at Silver City, in 1941.

Eureka district (see also Hidalgo County).—The output from the Grant County part of the Eureka district in 1941 comprised small lots of ore (mostly lead-silver) shipped through Ira L. Wright of Silver City from the American, Cherokee, Green Horn, and Hornet claims.

Pinos Altos district.—Zinc was the metal of chief value produced in the Pinos Altos district in 1941; most of it was contained in old tailings from the Cleveland dump shipped to the Peru mill at Deming. Some zinc-lead ore was treated in the 20-ton Calumet mill, and 19 tons were shipped from the Silver Hill mine to the Combination mill near Hanover. Gold-silver and gold-silver-lead-copper ores were shipped (mostly in small lots) to the El Paso smelter, Ira L. Wright at Silver City, and Hawley & Hawley at Douglas, Ariz., from various mines, dumps, and prospects in the Pinos Altos district. Among those producing more than 25 tons of ore were the Langston, Lupita No. 2, Pacific, and Wild Bill. Most of the output of placer gold from the Pinos Altos district in 1941 was recovered by Cooperative Placers, which operated a dragline land dredge in Santa Domingo Gulch.

Steeple Rock district.—The Southwest Mineral Co. operated the Carlisle group from January 2 through December 1941 and produced 11,313 tons of gold-silver-copper ore, of which 7,913 tons were concentrated in the company 75-ton flotation mill at Duncan, Ariz., and 3,400 tons were shipped crude to the El Paso smelter. Mine development done included a 300-foot vertical shaft and 250 feet of drifts. The Exploration Syndicate, Inc., continued to operate the East Camp group; most of the ore produced was treated in the company cyanide mill at the mine, and the gold-silver bullion recovered was shipped to the Denver Mint; a few cars of crude ore were shipped to the El Paso smelter. Other shippers of crude ore to the El Paso smelter or the International Smelting & Refining Co. smelter at Miami, Ariz., were the Eureka group, Homestake, Jim Crow, Laura, Mount Royal, New Year's Gift, and Ontario.

Swartz (or Carpenter or Camp Monarch) district.—The Black Range Development Co. worked the Grandview group from January through April 1941 and produced 502 tons of ore averaging 11.6 percent zinc, 7.1 percent lead, and 0.4 percent copper, and 1.1 ounces of silver and 0.003 ounce of gold to the ton; the ore was sold to the Combination mill near Hanover.

Telegraph district.—Small lots of lead-silver and silver ore were shipped through ore buyers (Ira L. Wright at Silver City and Hawley & Hawley at Douglas, Ariz.) from the Calard No. 2, Cora Miller, and Slate Creek claims.

White Signal district.—Only small-scale intermittent mining was done in the White Signal district in 1941, and the ore produced (mostly copper-silver) was shipped crude through Ira L. Wright at Silver City to El Paso or direct to the United Verde smelter at Clarkdale, Ariz. Among the producing lode claims were the Big Chief, Bisbee, Combination, Reward, and True Blue No. 1. Sluicing in Gold Gulch recovered a little placer gold.

GUADALUPE COUNTY

Alex. Bonnyman, Jr., worked the Stauber mine, in secs. 6 and 7, T. 7 N., R. 20 E. of the New Mexico principal meridian, under lease throughout 1941 and shipped to the El Paso smelter 2,411 tons of ore averaging 4.41 percent copper and 0.097 ounce of silver to the ton.

HIDALGO COUNTY

Eureka (Sylvanite) district (see also Grant County).—Small tonnages of smelting ore were shipped in 1941 from the Hardscrabble group and the Howell and Rincon claims.

Gillespie (Red Hill) district.—The Hope Mining Co., lessee at the Red Hill group, shipped 88 tons of lead-silver ore containing a little gold and copper to the El Paso smelter in 1941.

Lordsburg district.—The Banner Mining Co. operated the Bonney mine and 500-ton flotation mill 6 miles south of Lordsburg continuously in 1941. The ore produced from the various levels of the mine is hoisted through a 1,300-foot vertical main shaft 100 feet from the mill. The product of the mill is copper-gold-silver-[iron] concentrates, which are sold to the El Paso smelter. During the year the company unwatered the old Anita mine about 5 miles west of Lordsburg, reconditioned the 800-foot shaft, and began doing development work. The ore will be hauled to the mill at the Bonney mine for treatment. A road connecting the two properties was built. J. A. Werme shipped 55 tons of zinc-lead ore from the leased Ruth property to the Combination mill at Hanover (Grant County). Small lots of direct-smelting ore were shipped from the Blue Bird No. 2, C. G. N. S., and Francis K. Sweet claims.

San Simon district (Steins).—The McGhee 75-ton flotation mill at the McGhee mine 3 miles south of Steins was operated part of 1941 on zinc-lead-silver ore from the Crystal group. About 2 cars each of lead-silver concentrates and zinc concentrates were produced and shipped.

LINCOLN COUNTY

Cedar Creek district.—A lessee worked the Silver Cap No. 2 claim on a small scale in the spring of 1941 and produced some silver-lead-

copper ore, most of which was concentrated in the 20-ton mill on the property.

Jicarilla district.—Placer miners continued to recover gold in 1941 by dry washing, rocking, and sluicing in the Jicarilla Mountains southeast of Ancho.

White Oaks district.—A few cars of gold-silver ore were shipped from mines in the White Oaks district to the El Paso smelter in 1941.

LUNA COUNTY

Cooks Peak district.—Small tonnages of lead-silver ore were shipped through Ira L. Wright at Silver City in 1941 from the Busted Banker, Ethel-"85", Gladys, Graphic, and Mickey properties.

Deming.—In 1941 the Peru Mining Co. operated continuously its 500-ton selective-flotation mill at Wemple near Deming and treated mostly company zinc ore from the Pewabic mine in the Central district, Grant County, with some custom ore from the Central and Pinos Altos districts in Grant County. The output of zinc concentrates from the mill increased 50 percent over 1940.

SANTA FE COUNTY

Ortiz Mountains district (Cerrillos).—The only output from lode mines in the Ortiz Mountains district in 1941 was 42 tons of gold-silver-copper ore shipped from a prospect. Sluicing and dry washing on the Ortiz Grant southeast of Cerrillos recovered small lots of placer gold.

San Pedro or New Placers district.—Raskob Mining Interests, Inc., operated its San Pedro mine and 150-ton flotation mill from January 1 to August 15, 1941, and treated 26,554 tons of ore yielding 2,445 tons of concentrates containing 838 ounces of gold, 17,317 ounces of silver, and 1,496,780 pounds of copper. A lessee worked the Candelari mine on a small scale and trucked the ore produced 3½ miles to his 25-ton amalgamation-concentration mill at Golden for treatment. At the Old Timer mine 200 tons of ore were treated in a Huntington mill. Small quantities of gold were recovered from other lode mines and prospects in the San Pedro district. Individuals continued to work placer mines in the vicinity of Golden with sluices and dry washers.

SIERRA COUNTY

Chloride (Apache, Cuchillo Negro) district.—Only intermittent small-scale mining was done in the Chloride district in 1941. The ore produced was shipped in small lots direct to the El Paso smelter, or through Ira L. Wright at Silver City to El Paso and Hawley & Hawley at Douglas (Ariz.) to the Douglas smelter. Among the producing properties were the Apache group, Depression, Minnehaha, and New Era.

Kingston district.—Small tonnages of smelting ore were shipped from the Comstock, B. R., and Virginia properties in 1941.

Las Animas district (Hillsboro).—The Black Dome Mining Corporation built a 60-ton gravity- and flotation-concentration mill on Percha Creek 1 mile east of Hillsboro and operated it about 5 months in 1941 on ore and old tailings from the Snake-Opportunity-Litel King group and the Golden Era and Biglow mines. The mill feed totaled 4,300 tons, comprising 300 tons of newly mined ore and 4,000 tons of old tailings. The concentrates produced, containing gold,

silver, copper, and a little lead, were sold to the El Paso smelter. The Black Peak Mining Co. operated the Wicks mine a few months and shipped several cars of gold-silver-copper ore. Among the shippers of less than a car of ore during the year were the Duke, Tressness (formerly Garfield-Butler), and Tremont groups.

The John I. Hallett Construction Co. continued throughout 1941 to operate its movable dry-land Coulter-Ainlay four-bowl gold-recovery plant on placer ground 6 miles northeast of Hillsboro. The excavating unit consists of two butane-powered draglines of 1 and 1¼ cubic yards capacity, respectively. Drift mining at the Jones Hill placer and sluicing at other placers in the Hillsboro district recovered some gold.

Pittsburg and Caballos Mountains district.—Individuals, local and itinerant, panned for gold in 1941 on placer ground in the Pittsburg and Caballos Mountains district; the yield was sold through the Myers Co. store at Hatch.

SOCORRO COUNTY

Magdalena district.—The output of recoverable zinc from the Magdalena district rose from 411,000 pounds in 1940 to 5,159,000 pounds in 1941 and lead from 129,000 to 847,400 pounds. On April 1, 1941, Raskob Mining Interests, Inc., took an option on the Waldo mine and 200-ton flotation mill, owned by The Sherwin-Williams Co., and began preparing them for operation. The mine had been idle and full of water for many years. Pumping was begun in June, and the mine and mill were placed upon an operating basis in September; unwatering of the mine, however, was not completed until February 1942. Ore milled in 1941 totaled 20,211 tons, yielding 3,206 tons of concentrates averaging 53.2 percent zinc and 3.5 percent lead; the concentrates were shipped to the Ozark Smelting & Mining Co. pigment plant at Coffeyville, Kans. The Kelly mine of the Empire Zinc Co. was worked by lessees, who shipped zinc-lead ore to the Empire Zinc Co. flotation mill at Hanover and the Ozark Smelting & Mining Co. pigment plant, and lead-silver ore to the El Paso smelter. Victor Papa shipped 264 tons of lead-silver-gold-copper ore from the Papa property to the El Paso smelter; a few lots of lead-silver ore were shipped from prospects.

Mocking Bird district.—From July to December 31, 1941, the Mocking Bird Mining Co. drove a 250-foot incline shaft at the Mocking Bird group (formerly Independence group) and produced 811 tons of lead ore, which was concentrated in the company jig-concentration mill built in 1941 at Tokay (7 miles southeast of San Antonio) 28 miles from the mine. The mill recovered 54 tons of concentrates averaging 58.34 percent lead and 1.69 ounces of silver to the ton.

Rosedale district.—Bullion containing 35 fine ounces of gold and 128 fine ounces of silver was shipped from the Rosedale mine to the Denver Mint in 1941.

San Mateo Mountains district.—Ellison Warren shipped 52 tons of gold-silver ore to the El Paso smelter in 1941.

Silver Mountain (or Water Canyon) district.—Test runs made in 1941 on ore from the Open Cut mine, in the gravity-concentration mill on the property, yielded some gold and silver. A little gold was recovered from the Springtime claim.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN OREGON

(MINE REPORT)

By Charles White Merrill and H. M. Gaylord

SUMMARY OUTLINE

SUMMARY

After an all-time record in 1940, the total value of gold, silver, copper, and lead recovered from ores, old tailings, and gravels in Oregon declined 13 percent in 1941. Rising wages, migration of miners to war industries, rising costs of supplies and materials and difficulties in obtaining them, higher taxes, and fixed prices for gold and silver were factors in reversing a trend that had more than doubled the total value of the four metals since 1937.

The total value of the gold, silver, copper, and lead (in terms of recovered metals) produced in Oregon was $3,602,468 in 1941 compared with $4,148,271 in 1940. It was divided among the metals as follows: Gold, 94 percent; silver, 5 percent; and copper and lead combined, 1 percent. No recovery of zinc has been reported since 1937. Baker County continued to be the leading metal producer and contributed 42 percent of the State total value; Grant County yielded 30 percent, Jackson County 15 percent, Josephine County 8 percent, and the other 11 producing counties 5 percent. Distribution of production by counties was much the same as in 1940.

Cornucopia Gold Mines, which worked the Cornucopia mine in the Cornucopia district of Baker County until October 31, not only continued in 1941 to be the largest producer of lode gold in Oregon but also led again in output of total gold and copper. Although the Cornucopia operation was the largest to be suspended during 1941, other important producers also closed—Cougar-Independence Lessees, Western Dredging Co., Ferris Mining Co. (dragline dredge on Bull Run Creek in Baker County), Rogers & McGinnis, H. F. England Co. (dragline dredge on Dixie Creek in Grant County and Trout Creek in Harney County), and Murphy-Murray Dredging Co.

Despite a 19-percent decline in quantity of gold recovered by dragline dredging compared with 1940, this method continued for the third successive year to be the most important source of placer gold in Oregon; gold output from connected-bucket dredges declined only 3 percent; and production by nonfloating washing plants (to which gravel was delivered by mechanical means), hydraulicking, small-scale

hand methods, and underground gravel-mining all decreased substantially.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are bank measure; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052

1941	153	14,646,000	60,430	2,115,050	.144

[1] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[2] Includes all placer operations using dragline excavator for delivering gravel to floating washing plant
[3] Includes all placer operations using suction pump for delivering gravel to floating washing plant, except those producing less than 100 ounces of gold, which are included under "Small-scale hand methods", no suction dredges reported for 1937–40, inclusive.
[4] Includes all placer operations using power excavator and washing plant, both on dry land, when washing plant is movable, outfit is termed "dry-land dredge."
[5] Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dip boxes, pans, etc.
[6] None reported for 1937.
[7] A mine using more than 1 method of recovery is counted but once in arriving at total for all methods.

Gold.—Production of gold in Oregon in 1941 decreased 15 percent compared with 1940—the output from placers 16 percent and that from lode mines 14 percent. Of the total placer gold, dragline dredges recovered 47 percent, connected-bucket dredges 40 percent, nonfloating washing plants with mechanical excavators almost 5 percent, and hydraulicking and small-scale hand methods 4 percent each; recoveries by suction dredging and drift mining were relatively unimportant. Virtually all the lode gold was derived from dry ores and most (93 percent) of it from dry gold ore. Although 244 properties produced in 1941, the bulk of the gold came from relatively few mines; the following 10 properties, listed in order of output, supplied 62 percent of the State total: Cornucopia Gold Mines (gold ore), Sumpter Valley Dredging Co. (connected-bucket dredge), Porter & Co. (connected-bucket dredge), Cougar-Independence Lessees (gold ore), Northwest Development Co. (dragline dredge), Lewis Investment Co. (gold ore), the B-H Co. (dragline dredge), John Arthur (Cracker Creek group) (gold ore), Consuelo Oregon Mines (dragline dredge), and Charles C. Stearns (Alaska of Oregon) (dragline dredge). Operations at 2 of these, yielding over one-third of the gold production of the 10, were suspended before the end of 1941.

Silver.—Silver production in Oregon in 1941 increased 26 percent over 1940. Of the State total, Grant County contributed 35 percent, Jefferson County 32 percent, and Baker County 30 percent; dry gold-silver ore yielded 60 percent, dry gold ore 35 percent, placer gravel 4 percent, and silver and base-metal ores 1 percent. Nearly 61 percent of the total lode silver was recovered by concentration followed by smelting of the resulting concentrates; virtually all the rest of the output came from smelting of ore.

Copper, lead, and zinc.—Most of the copper output of Oregon in 1941 was a byproduct of ores worked primarily for their gold content. The lead output of the State, which totaled only 118,000 pounds, was derived entirely from precious-metal ores. No zinc was reported recovered.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, and lead in Oregon in 1941, by counties, in terms of recovered metals

County	Mines producing [1]		Gold					
			Lode		Placer		Total

[2] Sources of total silver as follows: 1941, 264,953 ounces from lode mines and 11,205 ounces from placers: 1940, 206,317 ounces from lode mines and 12,795 ounces from placers.
[3] Output from property not classed as a "mine"
[4] Morrow and Wheeler

MINING INDUSTRY

Of the 98,160 tons of ore (including 1,185 tons of old tailings) sold or treated in Oregon in 1941, Baker County produced 38,448 tons or 39 percent, Grant County 31,788 tons (including 50 tons of old tailings) or 32 percent, and Josephine County 22,711 tons (including 625 tons of old tailings) or 23 percent. Over 89 percent of the ore was dry gold ore, and virtually all the remainder was dry gold-silver ore. In addition to the ore, 1,185 tons of old tailings, of value principally in gold, were treated.

The seven properties worked by connected-bucket dredges had one dredge each, none of which worked at more than one Oregon property during 1941; at the end of the year two operations had been suspended. Among the properties worked by dragline dredges, however, one had two dredges, and a number of the dredges worked more than one property; in consequence, 16 dragline outfits worked 25 properties. At the close of 1941, however, only 12 dragline dredges were in operation. The dragline excavators were equipped as follows: 4 with 1¼-cubic yard buckets, 3 with 1½-cubic yard buckets, 2 with 2-cubic yard buckets, and 1 each with a 5-, 3½-, 3-, 2½-, 1⁹⁄₁₀-, 1¾-, and ½-cubic yard bucket.

Reports on the use of quicksilver at Oregon placer mines indicate that 1,108 pounds were consumed during 1941. The four connected-bucket dredges reporting on such use showed none consumed in 1941; the largest of the four reported enough quicksilver regained from gravel tailings to compensate losses in handling virgin ground. For the 17 dragline dredges reporting on the use of quicksilver a recovery of 55 ounces of gold per pound was recorded, compared with a recovery of 51 ounces in 1940 and 42 ounces in 1939. The quantities of gold recovered per pound of quicksilver used at other types of placer operations in 1941 were as follows (1940 figures in parentheses): Nonfloating washing plants with mechanical excavators, 43 ounces

(13); hydraulic mines, 21 ounces (22); and small-scale hand operations, 6 ounces (5).

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore and old tailings sold or treated in Oregon in 1941, with content in terms of recovered metals

Source	Material sold or treated		Gold	Silver	Copper	Lead
	Ore	Old tailings				
	Short tons	*Short tons*	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*
Dry and siliceous gold ore	86,563	1,185	33,542	96,607	103,900	84,000
Dry and siliceous gold-silver ore	9,779		2,583	165,948	14,100	34,000
Dry and siliceous silver ore	4			178		
Copper ore	629		10	2,220	48,000	
Total, lode mines	96,975	1,185	36,135	264,953	166,000	118,000
Total, placers			60,430	11,205		
	96,975	1,185	96,565	276,158	166,000	118,000
Total, 1940	102,250	3,219	113,402	219,112	176,000	70,000

METALLURGIC INDUSTRY

Of the State total ore and old tailings (98,160 tons), 66 percent was treated in concentrating mills, most of which used flotation; 25 percent was treated in amalgamation and cyanidation mills, with or without concentration equipment; and 9 percent was shipped crude to smelters. Ultimate recovery of 71 percent of the total lode gold was from the smelting of concentrates; 15 percent from direct smelting of ore; 11 percent as bullion from cyanidation of ore, old tailings, and concentrates; and 3 percent as bullion from amalgamation of ore. All material requiring smelting was shipped out of the State, as Oregon has no smelters.

Data furnished by operators of gold and silver mills show that 6,526 pounds of 91-percent sodium cyanide were consumed in recovering 3,899 ounces of gold and 276 ounces of silver from 20,529 tons of ore, 250 tons of old tailings, and 10 tons of concentrates, and that 7 pounds of quicksilver were used in recovering 449 ounces of gold and 116 ounces of silver from 166 tons of ore.

Mine production of metals in Oregon in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead
	Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*
Ore amalgamated	1,440	971	222		
Ore, old tailings, and concentrates cyanided	22,802	4,056	513		
Concentrates smelted:					
Flotation	6,279	25,485	160,856	88,200	83,200
Gravity	96	111	470	24,000	800
Ore smelted	8,896	5,512	102,892	53,800	34,000
Total, lode mines		36,135	264,953	166,000	118,000
Total, placers		60,430	11,205		
		96,565	276,158	166,000	118,000
Total, 1940		113,402	219,112	176,000	70,000

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Oregon in 1941, by types of mills and by counties, in terms of recovered metals

AMALGAMATION MILLS

[1] Only those counties and districts shown separately for which Bureau of Mines is at liberty to publish figures; others producing listed in footnote 10 and their output included under "Combined counties and districts."
[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[3] Source of total silver as follows: 264,953 ounces from lode mines and 11,205 ounces from placers.
[4] Greenhorn district lies in both Baker and Grant Counties.
[5] Mormon Basin district lies in both Baker and Malheur Counties.
[6] Output from a property not classed as a "mine."
[7] Greenback district lies in both Jackson and Josephine Counties.
[8] Included under "Combined counties and districts."
[9] Exclusive of lode output, which is included under "Combined counties and districts."
[10] Includes following districts: North Fork John Day in Grant County; Elk Creek in Jackson County; Illinois River (lode) in Josephine County; Columbia River in Morrow County; and Spanish Gulch in Wheeler County.

BAKER COUNTY [1]

Baker district.—The Midas mine in the Pocahontas section of the Baker district was worked by hydraulic mining during 1941; 198 ounces of gold and 21 ounces of silver were recovered from 6,585 cubic yards of gravel.

Bull Run district.—The Ferris Mining Co. operated a dragline dredge, using a dragline excavator with a 3-cubic yard bucket, on Bull Run Creek 6 miles southwest of Unity from January 1 until July 31, 1941; 485,270 cubic yards of gravel yielded 1,632 ounces of gold and 197 ounces of silver.

Cornucopia district.—The Cornucopia mine, operated by Cornucopia Gold Mines, continued to be the outstanding producer of lode gold, total gold, and copper in Oregon in 1941, although the company suspended operations October 31. Flotation of 30,800 tons of gold ore yielded 1,648 tons of gold concentrates containing 14,509 ounces of gold, 68,408 ounces of silver, 76,093 pounds of copper, and 21,744 pounds of lead; these concentrates and 8 tons of crude ore containing 6 ounces of gold, 38 ounces of silver, and 89 pounds of copper were shipped to a smelter. In terms of recovered metals, the mine supplied 40 percent of the lode gold produced in the State, 15 percent of the total gold, 25 percent of the silver, 45 percent of the copper, and 12 percent of the lead. The decline in production at this mine from its 1940 output was a major factor in the decreased gold and copper output in Oregon. A lessee shipped 1,046 tons of ore from the Simmons group for treatment at the Cornucopia flotation mill; the concentrates recovered were credited with a content of 264 ounces of gold and 1,840 ounces of silver.

Cracker Creek district.[2]—A smelter shipment of 217 tons of ore containing 236 ounces of gold, 64 ounces of silver, and 385 pounds of copper was made from the Argonaut mine in 1941. A lessee shipped 5,163 tons of smelting ore containing 2,828 ounces of gold, 7,776 ounces of silver, and 12,007 pounds of copper from the Columbia, Tabor Fraction, E & E, and North Pole mines.

Greenhorn district.—The Sunshine Mining Co. (Burnt River Division) installed a Yuba electric connected-bucket dredge with 4½-cubic foot buckets near Whitney and began operations October 21, 1941; treatment of 150,000 cubic yards of gravel yielded 391 ounces of gold and 80 ounces of silver. The Oroplata Mining Co. operated a dragline dredge on Pinus and Camp Creeks 3 miles north of Whitney.

Sumpter district.—Consuelo Oregon Mines operated a dragline dredge on McCully Fork. The Northwest Development Co. began 1941 with two dragline dredges operating in the Sumpter district, but only one dredge worked after February 28; 900,000 cubic yards of gravel yielded 5,701 ounces of gold and 1,324 ounces of silver. The Sumpter Valley Dredging Co., in 1941 again the largest producer of placer gold in Oregon, washed 3,376,514 cubic yards of gravel and recovered 9,178 ounces of gold and 1,923 ounces of silver; the dredge is of the connected-bucket electric-power type, with seventy-two 9-cubic foot buckets.

---

[2] Leaver, E. S., Woolf, J. A., and Towne, A. P., Progress Reports—Metallurgical Division. 46. Ore-Testing Studies (Primarily Precious Metals): Bureau of Mines Rept. of Investigations 3569, 1941, pp. 29–35.

Virtue district.—Lessees worked the Cliff mine during 1941; 65 tons of ore treated by amalgamation yielded 13 ounces of gold and 3 ounces of silver, and 279 tons of ore shipped to a smelter contained 190 ounces of gold, 97 ounces of silver, and 1,386 pounds of copper. During the first 5 months of the year, lessees on the Hidden Treasure mine shipped to a smelter 247 tons of ore containing 184 ounces of gold, 24 ounces of silver, and 468 pounds of copper; 80 tons of ore treated by cyanidation yielded 15 ounces of gold and 2 ounces of silver.

GRANT COUNTY [3, 4]

Canyon district.—On November 9, 1941, the Ferris Mining Co resumed operations with a dragline dredge, using a dragline excavator with a 3-cubic yard bucket, on the John Day River 3 miles northwest of John Day and continued until the end of the year; 130,370 yards of gravel yielded 683 ounces of gold and 72 ounces of silver. The Western Dredging Co. operated a connected-bucket dredge with seventy-two 6-cubic foot buckets from January 1 until October 4.

Granite district.—Porter & Co. operated a connected-bucket dredge with sixty-two 4½-cubic foot buckets on Granite, Clear, Olive, and Crane Creeks throughout 1941. The Intermountain Mining Co. abandoned dragline-dredge operations in the Granite district during the year. Bruce Dennis operated the Constitution mine; gold ore was treated in a 25-ton flotation plant, and gold concentrates and a small quantity of high-grade ore were shipped to a smelter. Cougar-Independence Lessees worked the Cougar Independence mine until September 1, when operations were suspended; gold ore was treated by flotation, and gold concentrates were shipped to a smelter. Rogers & McGinnis operated the La Bellevue mine from January 1 until November 15; gold-silver ore was treated in a 35-ton flotation plant, and gold-silver concentrates were shipped to a smelter. In addition to a substantial output of gold and silver, this operation led in the State in production of lead.

Greenhorn district.—Gold ore from the Morning mine, in that part of the Greenhorn district extending into Grant County from Baker County, was shipped to a smelter in 1941.

North Fork John Day district.—Ralph Davis, Inc., operated a dragline dredge, using a dragline excavator with a 3½-cubic yard bucket, at the North Fork placer from March 22 to December 24, 1941.

Quartzburg district.—The H. F. England Co. operated a dragline dredge with a dragline excavator, having a 1⅗₀-cubic yard bucket, on hydraulic tailings in Dixie Creek for 3 months in 1941; 150,000 cubic yards of gravel yielded 1,247 ounces of gold and 161 ounces of silver.

Susanville district.—The Timms Gold Dredging Co. operated its reconstructed connected-bucket dredge on the DeWitt ranch during 1941.

HARNEY COUNTY

Idol City district.—The H. F. England Co. operated a dragline dredge, moved from the Quartzburg district in Grant County to Trout Creek, for 2 months in 1941; 294 ounces of gold and 97 ounces of silver were recovered from old hydraulic tailings.

[3] Pardee, J. T., Work cited in footnote 1.

[4] *See also* State of Oregon Department of Geology and Mineral Industries, Oregon Metal Mines Handbook: Bull. 14-B, 1941, 157 pp

JACKSON COUNTY

Gold Hill district.—The Murphy-Murray Dredging Co. operated a connected-bucket dredge until September 22, 1941, when operations were discontinued; the dredge was dismantled and moved. Oregon Placer Mines, Inc., operated a dry-land dredge on Galls Creek from February 20 to July 6; 30,000 cubic yards of gravel yielded 198 ounces of gold and 38 ounces of silver. The Pleasant Creek Mining Corporation operated a connected-bucket dredge on Pleasant Creek.

Jacksonville district.—The Jackson Mining Co. operated a nonfloating washing plant with 4 Ainlay bowls, to which gravel was delivered by a 2-cubic yard dragline excavator, on the George Wendt ranch from May 15 to December 22, 1941.

Upper Applegate district.—Charles C. Stearns operated a dragline dredge on the Alaska of Oregon mine from January 8 to December 23, 1941. The B-H Co. operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, on Forest Creek; Stearns worked also on this property with a dragline dredge for a short time, and, in addition, conducted dragline dredging on the Herriot, Kubli, M. E. Dunlap, Walter W. Bell, and William Smith properties for short periods. The Crescent Pacific Mining Co. operated a dragline dredge, with a dragline excavator having a 1¾-cubic yard bucket, on the Fred Offenbacher, Matney, and Offenbacher ranches during 1941; 42,500 cubic yards of gravel at the Fred Offenbacher ranch yielded 244 ounces of gold and 33 ounces of silver, 88,825 cubic yards of gravel at the Matney ranch yielded 448 ounces of gold and 64 ounces of silver, and 455,770 cubic yards of gravel at the Offenbacher ranch yielded 1,490 ounces of gold and 195 ounces of silver. The Southern Oregon Mining Co. worked the McDonough and Taylor properties with a dragline dredge, using a dragline excavator with a 1¼-cubic yard bucket; 180,000 cubic yards of gravel at the McDonough ranch yielded 703 ounces of gold and 92 ounces of silver; and 65,700 cubic yards of gravel at the Taylor ranch yielded 70 ounces of gold and 9 ounces of silver. A lessee on the Sterling mine hydraulicked 34,375 yards of gravel and recovered 208 ounces of gold and 30 ounces of silver.

JEFFERSON COUNTY

Ashwood district.—The Oregon King Mines, Inc., shipped 2,348 tons of gold-silver ore containing 945 ounces of gold, 88,823 ounces of silver, 14,465 pounds of copper, and 63,046 pounds of lead from the Oregon King mine to a smelter in 1941. This mine was the leading producer of silver and the second-largest producer of lead in the State.

JOSEPHINE COUNTY

Galice district.—The Lewis Investment Co. worked the Benton mine throughout 1941 and was again the third-largest producer of lode gold in the State; the ore was treated in a 60-ton countercurrent-cyanidation plant.

Grants Pass district.—McGuire & Lyons operated a suction dredge on Rogue River near Grants Pass during 1941; 27,000 cubic yards of gravel yielded 191 ounces of gold and 17 ounces of silver. The Northern California Dredging Co. operated a dragline dredge, using a

dragline excavator with a 1¼-cubic yard bucket, on Jump-Off-Joe Creek for 4 months in 1941.

Greenback district.—Hydraulicking was carried on at the Blue Channel mine in 1941 from January 1 to June 1 and from November 15 to December 31. The Buckskin Mining Co. property on Wolf Creek was operated by hydraulicking for 5½ months. Hydraulicking was carried on at the Columbia mine.

Waldo district.—C. R. Stout hydraulicked at the Esterly mine in 1941 from January 1 to July 15 and from December 1 to 31 and recovered 433 ounces of gold and 24 ounces of silver from 150,000 cubic yards of gravel. The Atlas Gold Dredging Corporation operated a dragline dredge on Althouse Creek from January 1 to March 16; 255,178 cubic yards of gravel yielded 648 ounces of gold and 82 ounces of silver. Messenger and Johnson hydraulicked 62,000 cubic yards of gravel at the Plataurica mine on the Illinois River and recovered 108 ounces of gold and 7 ounces of silver.

MALHEUR COUNTY

Malheur district.—Pacific Placers operated a dry-land dredge near Brogan during 1941.

Mormon Basin district.—Mormon Basin Placers treated gravel in a stationary washing plant at Colt Bros. Placers and recovered 318 ounces of gold and 46 ounces of silver from 13,000 cubic yards of gravel. Whitney and Boydstun worked the Lone Eagle mine with a caterpillar scraper and washing plant; 60,000 cubic yards of gravel yielded 353 ounces of gold and 62 ounces of silver. The Gold Flower Mining Co. operated a dragline excavator and portable nonfloating washing plant.

OTHER COUNTIES

Small outputs in 1941 were reported from Coos, Curry, Douglas, Lane, Marion, Morrow, Wallowa, and Wheeler Counties.

Details of production by counties and districts are given in the preceding table.

GOLD, SILVER, COPPER, AND LEAD IN SOUTH DAKOTA

(MINE REPORT)

By Chas. W. Henderson and S. A. Gustavson

SUMMARY OUTLINE

For many years the principal mineral industry of South Dakota has been lode gold mining, with subsidiary silver. Such minor minerals as columbo-tantalite, tin, and lithium minerals have been produced, and at present there is a project for developing a large low-grade manganese deposit. The gold and minor mineral area of the State is included in Custer, Lawrence, and Pennington Counties in the mountain group known as the Black Hills. A notable exception is the extensive low-grade manganese deposit near Chamberlain, Brule County, which in 1941–42 was being developed and processed by the Federal Bureau of Mines. The total production of recovered gold in South Dakota in 1941—600,637 fine ounces valued at $21,022,295, a 2-percent increase over 1940—has been exceeded only by the peak output of 618,536 ounces valued at $21,648,760 in 1939. Recovered silver in 1941, all a byproduct of gold mining, was 170,771 fine ounces valued at $121,437. No copper or lead was recovered in 1941.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35 00	$0.7735	$0 121	$0 059	$0 065
1938	35.00	[4] 646+	.098	046	.048
1939	35 00	[5] 678+	104	047	052
1940	35 00	[6] 711+	.113	050	.063
1941	35 00	[6].711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20 671835) per fine ounce.

[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938-41 Treasury buying price for newly mined silver.

[3] Yearly average weighted price of all grades of primary metal sold by producers.

[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

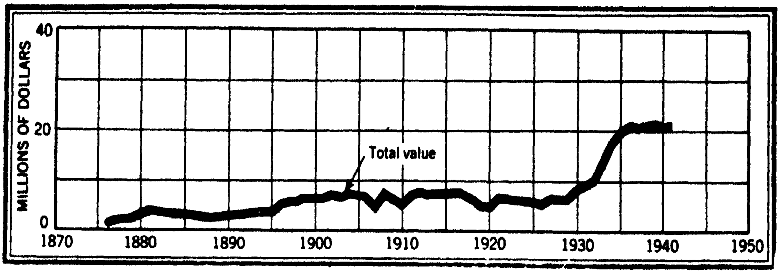

FIGURE 1.—Total value of mine production of gold and silver in South Dakota, 1876-1941.

MINE PRODUCTION BY COUNTIES

Mine production of gold and silver in South Dakota in 1941, by counties, in terms of recovered metals

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)		Total value
	Lode	Placer	Fine ounces	Value	Fine ounces	Value	
Custer		7	27	$945	1	$1	$946
Lawrence	6	13	596,109	20,863,815	169,891	120,811	20,984,626
Pennington	4	21	4,501	157,535	879	625	158,160
	10	41	600,637	21,022,295	170,771	121,437	21,143,732

MINING AND METALLURGIC INDUSTRY

Producers of lode gold and silver in South Dakota in 1941 mined and sold or treated 1,711,744 short tons of ore yielding, in recovered metals, 600,544 fine ounces of gold and 170,764 fine ounces of silver. Methods of treatment were as follows: 1,499,988 tons treated by amalgamation followed by cyanidation of sands and slimes; 205,356 tons by cyanidation only (36,677 tons of which was first roasted and about one-fourth of 134,985 tons also first roasted); 3,725 tons by jigging, amalgamation of the jig concentrates, and flotation of the remaining pulp (concentrates carrying gold and silver shipped to smelters); 100 tons by amalgamation only; 2,370 tons by amalgamation with flotation of tailing; 31,894 tons (included in 205,356 tons above) by countercurrent-decantation cyanidation with jig in ball-mill circuit (gold concentrates shipped to smelter); 200 tons by concentration; and 5 tons of crude ore shipped direct to the Omaha (Nebr.) refinery Operating details at both lode and placer mines are given in the following review by counties.

METALLURGIC RECOVERY

Gold and silver bullion produced at mills in South Dakota by amalgamation, 1937–41

Year	Ore treated	Gold in bullion	Silver in bullion	Quicksilver used
	Short tons	*Fine ounces*	*Fine ounces*	*Pounds*
1937	1,414,772	329,975.10	66,640	10,178
1938	1,430,391	328,044.50	62,602	7,744
1939	1,461,283	336,424.93	64,710	9,221
1940	1,479,905	313,964.15	60,254	4,997
1941	1,506,183	328,166.44	62,423	6,537

Gold and silver bullion produced at mills in South Dakota by cyanidation, 1937–41

Year	Material treated				Gold in bullion product	Silver in bullion product	Sodium cyanide used [1]
	Crude ore	Concentrates	Sands and slimes	Total			
	Short tons	*Short tons*	*Short tons*	*Short tons*	*Fine ounces*	*Fine ounces*	*Pounds*
1937	182,406		1,394,252	1,576,658	249,980.70	72,833	786,072
1938	155,667		1,416,899	1,572,566	262,913.21	98,777	860,762
1939	170,270	[2] 61	1,443,548	1,613,879	279,889.77	102,317	887,888
1940	187,360		1,432,244	1,619,604	269,518.82	111,607	883,849
1941	205,356		1,499,000	1,704,356	270,989.89	106,437	[3] 903,680

[1] In terms of 96- to 98-percent strength.
[2] From 1,143 tons of ore treated by flotation
[3] Actually 1,755,590 pounds of calcium cyanide (48- to 49-percent strength) and 28,445 pounds of sodium cyanide (91-percent strength); all reduced to equivalent of 96- to 98-percent strength to conform with earlier use of figures for high-strength NaCN and KCN.

REVIEW BY COUNTIES

CUSTER COUNTY

Small, hand-method, gold placering was done on seven properties, chiefly on French Creek, and constituted the only operations in Custer County in 1941. The gold recovered was sold either to local buyers or direct to the United States Mint at Denver, Colo. A large proportion of the placer ground in the county has been worked out and this, together with the fact that more jobs in other occupations are available, accounts for the small production of gold from the county.

LAWRENCE COUNTY

Homestake mine.—The Homestake mine has been an almost continuous producer of gold and silver since 1876 and has been operated by the Homestake Mining Co. since 1877. The company at first owned only the Homestake and Golden Star claims but has since acquired numerous others which, with the first two, have been consolidated into one group called the Homestake mine. The annual report of the general manager of the Homestake Mining Co. for the year ended December 31, 1941, says—

Operations during 1941 were substantially normal in all departments. Ore production from the mine was 1,499,988 tons which is an increase of 4.62 percent over that for 1940. The gross income for gold and silver produced was 2.70 percent higher than in 1940. The average realization per ton was $13.02 as compared to $13.26 in 1940.

Operating expenses exclusive of taxes were slightly higher than in 1940. Total taxes were $4,160,334.61, which is $570,990.29 more than in 1940.

There are 358,784 tons of broken ore remaining in shrinkage stopes.

The reserve of developed ore is 19,393,300 tons. As in previous reports this includes the broken ore. Of the total reserve 9,600,191 tons are in the ledge developed in recent years and 9,793,109 tons are in the main ledges. Production from the new ledge during 1941 was 310,813 tons or 20.72 percent of the total mined.

Yates shaft construction is practically completed. The shaft was completed to the 4,100-foot level late in December and sinking below that level is in progress. Ore hoisting at the Yates shaft began on October 1 and the handling of men and materials on November 10. All parts of this new plant are operating satisfactorily. The winze from the 4,100-foot level was deepened from the 4,700-foot evel to the 5,000-foot level and drifting on the 5,000-foot level was begun.

Ore milled, receipts, and dividends, Homestake mine, 1937–41 [1]

Year	Ore milled (short tons)	Receipts for bullion product		Dividends
		Total	Per ton	
1937	1,394,773	$19,304,076.45	$13.8403	$9,041,760
1938	1,377,314	19,284,459.67	14.0015	9,041,760
1939	1,400,015	19,922,964.60	14.2300	9,041,760
1940	1,433,737	19,014,767.73	13.2624	9,041,760
1941	1,499,988	19,529,080.70	13.0195	9,041,760

[1] From 1876 to 1941, inclusive, this mine yielded bullion and concentrates that brought a net return of $418,541,828 and paid $142,271,002 in dividends

The system of mining used at the Homestake mine has been described briefly as follows:[1]

The ore body is first cut by a series of stopes each extending for 60 feet along the strike and from wall to wall of the deposit—a distance which may be as great as

[1] Lincoln, Francis Church, Miser, Walter G., and Cummings, Joseph B., The Mining Industry of South Dakota: South Dakota Sch. Mines Bull. 17, February 1937, pp. 12–14.

400 feet. Pillars of ore 42 feet in thickness separate the 60-foot stopes. A stope is started by making a cut entirely across its bottom. A timbered gangway provided with chute gates is next constructed across the floor of the cut and waste filling is introduced around it. The stope is then carried upward by shrinkage stoping to within about 25 feet of the level above. The interval between levels is 100 feet in the upper part of the mine and 150 feet in the lower. During shrinkage stoping, the miners stand upon the broken ore, enough being drawn off regularly through the chute gates into the gangway to keep the ore away from the back and provide room for the miners to work. When shrinkage stoping is completed, the broken ore remaining in the stope is all drawn off, and the stope is filled with waste rock or mill tailings. The crowns of the stopes and the pillars between them are later mined by the square-set timbering system, the square sets being filled with waste.

Since 1932 sand fill (tailings from the sand plants) has been used to supplement the coarse waste fill.

The ore drops from the chutes into ore cars pulled by compressed-air locomotives and is taken to the shafts for hoisting. Primary crushing of the ore is done at the shafts. From the shafts the ore is moved by a rail tramway to the South mill, which has a capacity of 3,900 tons per 24 hours. Here the ore is reduced further by stamps and fed to rod mills in closed circuit with Clark-Todd amalgamators for primary grindings and to ball mills and pebble mills in closed circuit with Clark-Todd amalgamators for secondary grinding. The copper amalgamation plates, for many years an integral part of the mill equipment, gradually have been replaced by the Clark-Todd amalgamators. Classification is done partly in the South mill and is finished in cyanide sand plant No. 1 and cyanide sand plant No. 3. In plant No. 3 part of the sand tailings from the South mill are classified and ground further in ball mills in closed circuit with Clark-Todd amalgamators. The sands are treated by cyanide leaching, and the slimes are thickened and sent to the slime plant at Deadwood for further treatment. In plant No. 1 a partly classified sand portion of the tailings from the South mill is separated by cone classification into sand and slime fractions. In this plant the sands are leached, and the solutions from both this plant and plant No. 3 are precipitated. Slimes are piped to the slime plant at Deadwood, which accomplishes cyanidation of the slimes from both plants. Precipitation is by the Merrill-Crowe process. Silver is parted from the gold in the company refinery, and virtually pure metals are shipped to the mint.

The Homestake mine has been developed through shafts; the newest and deepest (4,100 feet) is the Yates which, to date, has cost over $3,000,000. In 1941 development work in the mine consisted of sinking 700 feet of shaft, driving 28,074 feet of drifts and crosscuts and 10,878 feet of raises, and performing 45,656 feet of diamond drilling.

Other mines.—The second-largest producer of gold and silver in South Dakota in 1941 was the Bald Mountain Mining Co. The company operated continuously its consolidated group of mines and 370-ton (rated 350 tons in 1940) all-sliming countercurrent-cyanidation plant at Trojan. Ore was produced in 1941 from the Portland, Two Johns, Dakota, Trojan, Clinton, and Empire claims. Development work done on these claims in 1941 totaled 2,695 feet of drifts and 630 feet of raises. The mill treated 134,985 tons of dry gold ore, from which 27,322 fine ounces of gold and 48,937 fine ounces of silver were recovered. Five tons of high-grade ore, containing 98 fine ounces of gold and 1,521 fine ounces of silver, were shipped direct to the Omaha (Nebr.) refinery. About 25 percent of the ore produced was sulfide

(locally known as "blue ore"), and 75 percent was oxide (locally known as "brown ore"). After primary crushing the sulfide ore was roasted in a 110-ton gas-fired rotary hearth furnace, then mixed with the oxide ore and cyanided. The net return from metals produced in 1941 after transportation and mint and smelter charges were deducted was $989,945.

The Canyon Corporation operated its Maitland group of claims and 120-ton (rated 100 tons in 1940) roast-cyanide mill continuously, treating 36,677 tons of ore which yielded 11,256 fine ounces of gold and 1,056 fine ounces of silver. Development work in the mine consisted of 2,754 feet of prospecting drifts, 2,257 feet of development drifts, and 4,354 feet of diamond drilling.

The Gilt Edge Mines, Inc., properties in the Bear Butte district were inoperative, except that clean-up in the mill and final settlement of product mined in 1940 carried over into 1941.

The Frerichs Mining Co. operated its mine and 50-ton flotation-cyanidation mill during January and February 1941, making test runs to try out equipment and determine best extraction. About 1,800 tons of ore were treated, which yielded 91 fine ounces of gold and 66 fine ounces of silver.

The Belle Eldridge Gold Mines, Inc., did some development work on its property in the Whitewood district and made repairs and installed some new equipment in the company mill.

Placers active in Lawrence County included two operations in the Bear Butte district, one in the Custer Peak, one in the Portland or Bald Mountain, one in the Rawlings, one in the Two Bit, and seven in the Whitewood district. All were small hand-sluicing and panning operations and produced a total of only 35 fine ounces of gold and 3 fine ounces of silver.

PENNINGTON COUNTY

The Holy Terror Mining Co. operated its mine and 100-ton cyanidation plant in the Keystone district continuously, treating 31,894 tons of dry gold ore. The mill process is countercurrent-decantation cyanidation, with a jig in the ball-mill circuit. Part of the jig concentrates was shipped to the Helena (Mont.) smelter. The gold-silver bullion was shipped to the Denver Mint. In the mine a development program was started to open up a level 200 feet below the 1941 workings.

In the Hill City district, the Gold Mountain Mining Co. operated part time its mill and the Gold Lode group of claims.

Two other small lode operations in Pennington County—one in the Hill City district and the other in the Hornblende district—treated a few tons of ore in small amalgamation mills; each recovered less than 2 fine ounces of gold.

Twenty-one placers in the county, all small hand-sluicing or panning operations, yielded a total of 31 fine ounces of gold and 3 fine ounces of silver in 1941. Operations were chiefly on Castle Creek in the Castle Creek district, Battle Creek in the Keystone district, and Rapid Creek in the Rapid Creek district.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN TEXAS

(MINE REPORT)

By Chas. W. Henderson and S. A. Gustavson

SUMMARY OUTLINE

Silver was found in Texas in 1880 at the Presidio mine at Shafter, Presidio County, but it was not until 1885 that shipments of bullion were begun. From 1885 through 1941 this mine has been by far the outstanding producer of the State—chiefly of silver but also of gold and lead. Another early producer was the Hazel mine in Culberson County. The American Metal Co. of Texas continued to operate the Shafter mine and 400-ton cyanidation mill in 1941 and made a slightly decreased tonnage output containing less silver to the ton than in 1940. About 200 tons of silver smelting ore (carrying some copper) from the Hazel mine and 18 tons of silver ore from the Needle Peak mine were shipped to the El Paso smelter. Of interest in 1941 was the shipment of 6 tons of copper ore from an open-cut on the Bob Cat location 10 miles south and 6 miles east of Quanah, Hardeman County, where copper ore has been reported for many years. A car of silver smelting ore, carrying some copper, was shipped from the Black Shaft mine near Allamoore, Hudspeth County, to the El Paso smelter. Smelting lead-silver ore, carrying some copper, was shipped from the Puerto Rico mine near Sierra Blanca, Hudspeth County, to El Paso.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35 00	$0. 7735	$0. 121	$0. 059	$0. 065
1938	35 00	[4] .646+	. 098	. 046	. 048
1939	35. 00	[5] .678+	. 104	. 047	. 052
1940	35 00	[6] . 711+	. 113	. 050	. 063
1941	35. 00	[6] . 711+	. 118	. 057	. 075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] 1937. Yearly average weighted Treasury buying price for newly mined silver, 1938–41: Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

MINE PRODUCTION

The following table shows the annual output of ore and the quantity and value of the metals recovered from Texas mines from 1937 to 1941, as well as the total metal production from 1885 to 1941.

Mine production of gold, silver, copper, lead, and zinc in Texas, 1937–41, and total, 1885–1941, in terms of recovered metals

Year	Ore (short tons)	Gold		Silver	
		Fine ounces	Value	Fine ounces	Value
1937	120,145	562	$19,670	1,325,660	$1,025,398
1938	131,002	439	15,365	1,433,008	926,389
1939	141,795	324	11,340	1,341,945	910,896
1940	146,936	312	10,920	1,326,150	943,040

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Texas in 1941, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)
Dry and siliceous silver ore	4	140,739	304	1,095,750	8,900	368,900
Copper ore	2	58		22	3,000	
Lead ore	3	21	2	255	100	3,100
	9	140,818	306	1,096,027	12,000	372,000
Total, 1940	6	146,936	312	1,326,150	60,000	410,000

SMELTING AND REFINING PLANTS IN TEXAS

In 1941 two zinc retort smelters, one copper smelter, one lead smelter, one antimony smelter, one tin smelter, and one electrolytic copper refinery were operating in Texas; and an electrolytic zinc refinery was under construction. The two zinc retort smelters and the electrolytic copper refinery were operated virtually at capacity throughout the year. While the copper and lead smelters were run somewhat under capacity, owing to lack of domestic ores and Mexican ores, advantage was taken of the situation to make improvements, repairs, and additions to both plants.

The American Smelting & Refining Co. continued to operate its copper and lead smelters at El Paso in 1941, treating ores purchased from operators in Arizona, California, New Mexico, and Texas and in Mexico. Also, ores from Canada, South America, Africa, and many other foreign countries were sent to the smelters at El Paso after their original destinations had fallen into enemy hands, and other ores captured by the British. Additional roasting facilities, other new equipment, and general repairs and improvements were made on both the lead and copper smelters during the year. In addition to the lead and copper furnaces the El Paso plant contains a unit for the recovery of arsenic.

The American Smelting & Refining Co. gas-retort zinc smelter at Amarillo was operated continuously at capacity throughout the year, treating zinc concentrates and some high-grade zinc ores purchased from operators in Arizona, Colorado, Nevada, New Mexico, and Utah, and in Mexico. Zinc concentrates from Newfoundland were treated under bond. Three blocks, each of 800-ton monthly capacity, were added to the plant early in the year, supplementing the five blocks already in use and increasing the capacity 60 percent. Roasting equipment at the plant was inadequate to handle the added retort capacity and necessitated preliminary roasting of Mexican ores at the company El Paso plant.

The Machovec smelter of the American Zinc Co. of Illinois at Dumas, Tex., was operated at capacity throughout the year on zinc concentrates from operators in New Mexico and in Mexico, and zinc concentrates from Newfoundland were treated under bond. Additions to the plant were made, increasing capacity 100 percent since it was again placed in operation in February 1940. The plant is leased from the Illinois Zinc Co.

The Nichols electrolytic copper refinery at El Paso, a unit of the Phelps Dodge Corporation, continued to refine copper anodes produced at corporation smelters in Arizona. The plant was operated virtually at capacity throughout the year.

MINES REVIEW BY COUNTIES

Culberson County.—The Hazel mine 14 miles northwest of Van Horn was operated by A. P. Williams under lease until March 20, 1941, when his lease expired. The mine was then operated by J. P. Witherspoon, with A. P. Williams acting as mine superintendent. In 1941 silver ore totaling 216 tons and containing 1,815 ounces of silver, 9,141 pounds of copper, and 433 pounds of zinc was shipped to the El Paso smelter. A small lot of 18 tons of dry silver ore containing 103 ounces

of silver was shipped also from Culberson County to the El Paso smelter.

Hardeman County.—A 6-ton lot of copper ore containing 440 pounds of copper was shipped to the El Paso smelter.

Hudspeth County.—The Black Shaft mine 8 miles south of Allamoore was operated 11 months during 1941 by A. P. Williams. Copper ore totaling 52 tons and containing 21 ounces of silver and 2,641 pounds of copper was shipped to the El Paso smelter. Three small lots of lead ore totaling 21 tons were shipped from Sierra Blanca to the El Paso smelter, mostly from the Puerto Rico mine.

Presidio County.—The American Metal Co. of Texas operated its Presidio property continuously in 1941; the quantity of ore treated was 140,503 tons compared with 144,558 tons in 1940. The mine is developed by two vertical shafts, one 400 and one 700 feet deep; three underground subshafts, one 100, one 250, and one 450 feet deep; and other openings reported as totaling 75 miles of underground workings. Development work in 1941 comprised 303 feet of shaft, 8,532 feet of drifts, and 27,808 feet of diamond drilling. The minerals contained in the ore are argentite, cerargyrite, galena, anglesite, and cerussite. The ore is transported 1¼ miles by rail and aerial tramways from the shafts to the 400-ton mill (average per day treated in 1941, 387 tons). In 1941 the mill produced 940,967 ounces of silver and 285 ounces of gold in cyanide precipitates, and 439 tons of table concentrates containing 152,781 ounces of silver, 19 ounces of gold, and 350,277 pounds of lead. The cyanide precipitates carried 26,065 pounds of lead dissolved by the cyanide, an unusual phenomenon. The concentrates and precipitates were shipped to the Carteret (N. J.) smelter.

Production of silver from the Presidio mine,[1] 1885–1941 [2]

Period	Mill heads treated (short tons)	Silver content of mill heads (ounces)		Recovery of silver	
		Per ton	Total	Percent	Ounces
1885–1912	450,000	25 84	11,628,000	81.68	9,497,750
1913–26	720,000	12 00	8,640,000	83 66	7,228,224

GOLD, SILVER, COPPER, LEAD, AND ZINC IN UTAH

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

SUMMARY

Utah mines produced gold, silver, copper, lead, and zinc in 1941 valued at $97,796,623, in terms of recovered metals. This value, compared with $86,585,499 in 1940, represents a 13-percent gain, which was due almost entirely to the increased output of recovered copper. The quantity of gold was virtually the same as in 1940; that of silver, lead, and zinc decreased, although the total value of both lead and zinc increased. The slight gain in gold and by far the largest part of the gain in copper output can be credited to the Bingham district and resulted from the outstanding efforts of the Utah Copper Co. The Park City region showed gains in production of gold and copper only, and the Tintic district made gains in output of lead and zinc. Tooele County reported a loss in output of each metal except zinc, which increased owing to the output from the Tooele slag-fuming plant.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4].646+	.098	.046	.048
1939	35.00	[5].678+	.104	.047	.052
1940	35.00	[6].711+	.113	.050	.063
1941	35.00	[6].711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] 1937: Yearly average weighted Treasury buying price for newly mined silver; 1938–41: Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Utah, 1937–41, and total, 1864–1941, in terms of recovered metals

[2] Short tons.

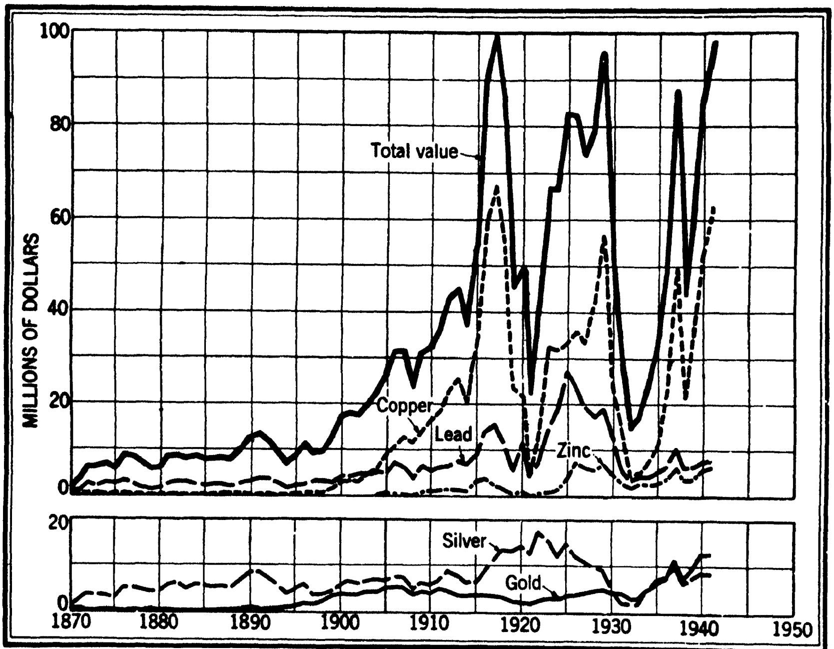

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc and total value in Utah, 1870–1941.

Gold.—The output of recoverable gold in Utah increased 1,007 ounces in 1941 from 1940. Copper ore yielded 68 percent of the total gold and siliceous ore 16 percent; the remainder came from zinc-lead ore, lead ore, lead-copper ore, zinc ore, zinc-lead-copper ore, and slag

and from placers. The placer output was negligible. Gold recovered from ore of all classes treated in concentrating mills comprised 80 percent of the State total, from crude ore shipped direct to smelters nearly 15 percent, and from ore treated by amalgamation and cyanidation and from placers 5 percent. The Bingham (West Mountain) district produced 77 percent of the State gold and showed a gain of 18,561 ounces. The Park City region produced 2,447 ounces more gold than in 1940, owing to the output of the New Park Mining Co. Gold produced from the Tintic district decreased sharply, owing chiefly to the decline at the Tintic Bullion and Centennial-Beck & Victoria mines, and gold output from Tooele County decreased 3,481 ounces. The Utah Copper Co., which supplied over 67 percent of the State gold, was followed by the group of properties at Mercur under control of Snyder Mines, Inc., and the United States & Lark, Mayflower, and Tintic Bullion mines; these five mines produced 88 percent of the total gold output of the State.

Silver.—Silver recovered from Utah ore totaled 11,395,485 ounces in 1941, a decrease of 776,814 ounces from 1940, owing primarily to the lower output of siliceous ore. In 1941 zinc-lead, lead-copper, and zinc-lead-copper ore yielded 51 percent of the State total silver, siliceous ore 20 percent, copper ore 20 percent, and lead ore nearly 9 percent. Bingham was again the largest silver-producing district (supplying 43 percent of the State total), followed by the Park City region, the Tintic district, and Tooele County. Ore concentrated yielded 70 percent of the State silver, and ore shipped crude to smelters nearly all the remainder. The Utah Copper Co. was again the largest producer, followed by the United States & Lark, Tintic Standard, Silver King Coalition, the Park City Consolidated properties, the New Park Mining Co. property, the Park Utah Consolidated Mines groups, and the Chief Consolidated properties; these eight properties produced 82 percent of the silver output of Utah in 1941.

Copper.—The output of recoverable copper in Utah during 1941 was 533.676,000 pounds, by far the greatest production in the history of the State; the previous high year was 1940, when the output was 463,728,000 pounds. The Utah Copper Co. exceeded its former high record set in 1940; its open-cut mine at Bingham produced about 68,000,000 tons of ore and waste at a ratio of about 1¼ tons of waste to 1 ton of ore. The company mills at Magna and Arthur treated ore at a combined rate of over 83,000 tons a day and showed high recoveries in copper; their rated capacity is approximately 68,000 tons a day. Copper ore mined in Utah totaled 30,444,402 tons in 1941 compared with 26,301,745 in 1940. Copper ore and mine-water precipitates yielded 99 percent of the State copper. Other producers of copper in Utah included the Ohio Copper Co. and the United States & Lark properties in the Bingham district and the Tintic Standard properties in the Tintic district.

During the first 4 months of 1942, Utah mines were producing at a rate which indicated that even the all-time high production of 1941 would be exceeded.

Lead.—The output of recovered lead in Utah was 139,202,000 pounds in 1941, a decline of 12,174,000 pounds from 1940. The Bingham district continued to be the largest lead-producing area in the State, although production declined 6,689,100 pounds from 1940; most of the output came from the United States & Lark properties. The

Park City region produced about the same quantity of lead as in 1940, but the average grade of the ore treated decreased slightly in 1941; the two leading producers of the district were the Silver King Coalition Mines Co. and the Park Utah Consolidated Mines Co. (including Daly), which together produced 195,291 tons of ore yielding 30,854,000 pounds of lead. The output from the Tintic district showed a gain, owing chiefly to increased production at the Tintic Standard mine, from which large quantities of siliceous ore and dump material were shipped direct to a smelter in 1941 for fluxing purposes. Output from the Calumet and Hidden Treasure mines in Tooele County decreased from 1940. The principal lead-producing mines in Utah in 1941 were the United States & Lark, Park Utah Consolidated (including Daly), Silver King Coalition, Tintic Standard, Calumet, New Park mines, and Chief Consolidated; these seven properties produced 81 percent of the State total lead.

Output during the first 3 months of 1942 indicates that lead is being produced at a rate that will result in a material gain over 1941.

Zinc.—The output of recoverable zinc in Utah during 1941 decreased 4 percent from 1940. The chief zinc-producing areas—the West Mountain district and the Park City region—each reported a loss, as both tonnage and grade were lower than in 1940. Zinc was recovered finally from zinc-lead ore treated at four selective-flotation mills, from zinc-lead-copper ore treated at two of the flotation mills, from the fuming of zinc-lead slag at Tooele, and from crude zinc and zinc-lead ore shipped direct to smelters. The United States & Lark property in the Bingham district was again the largest producer of zinc in the State, followed by the Park Utah Consolidated (including Daly) and Silver King Coalition properties in the Park City region, the Calumet property in Tooele County, and the New Park property in the Park City region; these five mines supplied 84 percent of the State zinc output in 1941.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Utah in 1941, by counties, in terms of recovered metals

County	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)

[1] Includes 629 ounces of placer gold distributed as follows: Garfield County, 4 ounces; Grand County, 252 ounces; Millard County, 21 ounces; San Juan County, 18 ounces; and Uintah County, 334 ounces.
[2] Includes 275 ounces of placer gold distributed as follows: Garfield County, 1 ounce; Grand County, 82 ounces; Millard County, 74 ounces; San Juan County, 35 ounces; and Uintah County, 83 ounces.

MINING INDUSTRY

Copper ore produced in Utah in 1941 (predominantly from the Bingham district) represented 95 percent of the total tonnage of ore of all classes. The Utah Copper Co., operating the open-pit mine at Bingham, began 1941 with a monthly output of about 42,000,000 pounds of copper, which had risen to about 46,000,000 pounds in December. This copper ore, carrying a low content of gold and silver, accounted for nearly all the district gain in gold and silver output. The Bingham district showed decreases in 1941 in both tonnage and grade of zinc-lead ore mined, the Park City region showed an increase in tonnage but a decrease in grade, and Tooele County showed a decrease in tonnage; but the Tintic district trebled its tonnage of zinc-lead ore. In 1941 the production of siliceous ores declined from that in 1940; the largest decreases were in the output of gold ore in Tooele County and of gold, gold-silver, and silver ores in the Tintic district. In 1941 these two regions supplied about 90 percent of the siliceous ore output of the State.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Utah in 1941, with content in terms of recovered metals

Source	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc
		Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*
Dry and siliceous gold ore	24	328,576	42,171	130,260	426,316	288,914	
Dry and siliceous gold-silver ore	33	199,866	12,091	946,277	899,469	5,983,069

[1] Includes 13,418,668 pounds recovered from mine-water precipitates.
[2] Includes 29,658 tons of zinc-lead slag.
[3] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.
[4] Includes 14,223,006 pounds recovered from mine-water precipitates.

METALLURGIC INDUSTRY

In 1941, 31,952,817 tons of Utah ores were treated—a quantity that exceeded the 1940 record output by 14 percent—as follows: 31,205,481 tons at concentrating mills compared with 27,215,217 tons in 1940; 252,080 tons at cyanidation mills compared with 297,567 tons in 1940; 515 tons at amalgamation mills compared with 520 tons in 1940; 465,083 tons shipped crude to smelters compared with 426,042 tons in 1940; and 29,658 tons of zinc-lead slag fumed compared with none in 1940. A considerable tonnage of siliceous ore, included in the quantity shipped crude to smelters, came from old dumps and tailings piles and was used primarily as a flux in smelting. The siliceous fluxing ores usually were sold upon a per-ton basis, and the shipper received further payments if the metal content exceeded certain base minimums established by the smelters.

All the ore cyanided was handled at two cyanide plants at Mercur, each treating considerable custom ore; the total (252,080 tons) yielded 17,804 ounces of gold and 65 ounces of silver. These two plants reported a consumption of 140,500 pounds of sodium cyanide (91-percent grade), 1,730,460 pounds of lime, and 26,991 pounds of zinc dust. Eleven concentrating plants were active in Utah during 1941—three plants (Arthur, Magna, and Ohio Copper) treated 30,432,336 tons of copper ore and old tailings; four mills (Bauer, Midvale, Silver King, and Tooele), having a combined rated daily capacity of 4,800 tons, treated 754,345 tons of ore mostly zinc-lead and zinc-lead-copper; three gravity-concentration mills (one in Beaver County, one in Tooele County, and one in Utah County) treated 800 tons of lead ore;

and one flotation mill in Summit County treated 18,000 tons of zinc-lead tailings. One slag-fuming plant at Tooele treated 29,658 tons of slag.

The following tables give details of treatment for all the ore produced in Utah in 1941.

Mine production of metals in Utah in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc
	Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*
Ore amalgamated	515	35	122			
Ore cyanided	252,080	17,804	65			
Concentrates smelted	1,073,438	286,575	7,973,147	516,364,567	108,895,218	83,920,987
Slag fumed	29,658					
Ore smelted	465,083	51,458	3,422,061	3,892,765	30,306,782	177,013
Mine-water precipitates smelted[1]	8,320			13,418,668

[1] Detroit district lies in both Juab and Millard Counties.

[2] Tintic district lies in both Juab and Utah Counties.

BEAVER COUNTY

Beaver Lake district.—A small shipment of silver-lead ore from the property of the Beaver Gold & Copper Co. comprised the output of the Beaver Lake district in 1941.

Bradshaw district.—Production in the Bradshaw district during 1941 came from a small lot of gold ore shipped crude to a smelter.

Rocky district.—The Prosper Mining Co. operated the Old Hickory group in 1941 and shipped 2 cars of gold-silver-copper ore direct to a smelter; the property was operated primarily for the tungsten content of the ore. Crude ore was shipped direct to a smelter from the Montreal property also.

San Francisco district.—The Horn Silver Mines Co. shipped lead ore crude to a smelter in 1941 and was the largest producer in the San Francisco district. Most of the remainder of the district metal output was from zinc ore from the King David property and lead ore from the Quad Metals Corporation property.

Star and North Star district.—The bulk of the district output came from zinc ore shipped from the Moscow Silver property to Tooele for treatment. Most of the remainder came from small shipments of lead, silver, and gold ore shipped crude to smelters from several properties.

BOX ELDER COUNTY

Ashbrook district.—Silver ore, all from the Vipont property, comprised virtually the entire output of the Ashbrook district in 1941.

IRON COUNTY

Calumet district.—Lead ore shipped crude to a smelter from the property of the New Arrowhead Mining Co. comprised the output from the Calumet district in 1941.

Stateline district.—Gold ore from the property of Aetna Gold Mines, Inc., treated by amalgamation, yielded most of the output from the Stateline district.

JUAB COUNTY

Detroit district.—The Ibex property shipped gold ore crude to a smelter in 1941 and accounted for the entire output from the Juab County section of the Detroit district.

Fish Springs district.—Lead ore shipped direct to a smelter from the Black Dragon and Utah Mine group comprised the output of the Fish Springs district in 1941.

Tintic district.—The Tintic district, which lies in both Juab and Utah Counties, is reviewed here. The table that follows gives the metal production in each section of the district for 1941, a comparison with the total output in 1940, and the grand total from 1869 to 1941.

In 1941 the Chief Consolidated Mining Co. operated the Chief No. 1, Gemini, Eureka Hill, and Plutus mines in Juab County. Development operations on the Apex Standard area were continued during the year but were suspended in January 1942 awaiting the receipt of premium metal quotas. Although most of the company output was contained in ore from the Chief No. 1 property, large tonnages of siliceous tailings were shipped to Garfield from the Eureka Hill and Chief No. 1 dumps. According to the company printed annual report, production of gold, silver, and copper decreased from that in

Mine production of gold, silver, copper, lead, and zinc in Tintic district, Juab and Utah Counties, Utah, 1940–41, and total, 1869–1941, in terms of recovered metals

	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc	Total value

1 Figures not available.

1940, but the output of lead and zinc increased. Production in 1941, says the report, comprised 34,397 tons of siliceous ore, 288 tons of silver-lead ore, and 12,619 tons of zinc-lead ore from the Chief No. 1 mine; 6,280 tons of siliceous ore and 382 tons of silver-lead ore from the Gemini mine; 2,086 tons of siliceous ore from the Eureka Hill mine; and 851 tons of siliceous ore and 28 tons of silver-lead ore from the Plutus mine—an aggregate of 56,931 tons of ore of all classes, which contained 2,115 ounces of gold, 361,832 ounces of silver, 74,436 pounds of copper, 1,448,574 pounds of lead, and 2,064,340 pounds of zinc. Total development work was 3,989 feet and included three major projects, none of which reached its objective. The Centennial-Beck, Victoria, and Eagle & Blue Bell properties, all owned or controlled by the United States Smelting, Refining & Mining Co., were operated on company account during the year; lessees worked the American Star mine until April 1941, when all operations stopped. The total production from these properties comprised 4,790 tons of lead ore and 13,309 tons of siliceous ore, all of which was shipped crude to smelters. The Dragon, Martha Washington, and the Empire group (formerly Empire-Star), all owned or controlled by the International Smelting & Refining Co., were operated in 1941 by lessees; the production was siliceous gold-silver ore shipped direct to a smelter. The Godiva mine, operated by a lessee, yielded 29,936 tons of ore of all classes, principally siliceous ore, which was shipped direct to a smelter. The Mammoth Mining Co. operated its property all of 1941 and shipped 20,533 tons of siliceous ore and 1,415 tons of lead ore direct to a smelter. The remainder of the output of the Juab County section of the Tintic district was predominantly siliceous ore shipped direct to smelters and came principally from the Windridge, Alaska, Showers, and Park Utah mines and the dump of the Grand Central mine.

The Tintic Standard Mining Co. and its subsidiary companies, largest producers in the Utah County section of the Tintic district in 1941, produced lead ore and siliceous ore. The printed annual report of these companies gives the following operating details. Ore production at the Tintic Standard mines (including the Iron Blossom) increased 12,118 tons over 1940. Most of the ore was siliceous in character and was mined on company account. The Eureka Lilly Consolidated mines produced 6,500 tons of ore, largely siliceous, which was mined chiefly by lessees; the Colorado Consolidated and Sioux mines were operated by lessees and produced 3,511 and 404 tons, respectively, chiefly

siliceous ore. The tonnage of ore of all classes aggregated 126,878 (92,630 tons was siliceous ore), which had the following metal content: 6,194 ounces of gold, 1,656,180 ounces of silver, 1,236,937 pounds of copper, and 13,186,346 pounds of lead; the siliceous ore averaged 2.5 percent lead. In addition, 31,673 tons of siliceous material from the Harold dump were shipped crude to Garfield; it contained over 1,000,000 pounds of lead. Development during 1941 totaled 5,669 feet of drifts and raises and 66 feet of shafts. During the year the lead ore shipped was higher in lead content, but substantially lower in silver; in the siliceous ores, the content of gold and silver was lower. Active mines in the Utah County section of the Tintic district, owned or controlled by the International Smelting & Refining Co. and its subsidiaries, were the Eureka Bullion, May Day (Mountain View), North Lily, Tintic Bullion, and Yankee.

West Tintic district.—Crude lead ore from the Scotia mine, operated by a lessee, comprised the output from the West Tintic district in 1941.

MILLARD COUNTY

Detroit district.—Siliceous gold ore shipped direct to a smelter comprised the output from the Millard County section of the Detroit district in 1941. The Charm mine was the principal producer.

MORGAN COUNTY

Argenta district.—Crude lead ore shipped direct to a smelter, principally from the Dan Heiners claim, comprised the output from the Argenta district in 1941.

PIUTE COUNTY

Gold Mountain district.—Lessees operating the property of Annie Laurie Consolidated Gold Mines, only producer in the Gold Mountain district in 1941, shipped 1,623 tons of gold ore to a smelter.

Mount Baldy district.—The property of the Deer Trail Mining Co., only producer in the Mount Baldy district in 1941, was operated by a lessee from July to the end of the year; 451 tons of siliceous ore were shipped direct to a smelter.

Ohio district.—Siliceous ore shipped crude to a smelter from the Bully Boy property of the American Mineral Products Co. was the only production from the Ohio district in 1941.

SALT LAKE COUNTY

Big and Little Cottonwood districts.—Lessees operated the Cardiff property in the Big Cottonwood district during 1941 and shipped 644 tons of ore—152 tons of lead ore, 368 tons of copper ore, and 124 tons of zinc-lead ore. The output from the Mountain Mines Co. property, second-largest producer in the district in 1941, totaled 200 tons of ore shipped crude to a smelter; the company completed the lower development tunnel and made contact with vein at 2,000-foot depth. Other producers in the district were the Utah-Kentucky Mines Co. and the Tar Baby Mining Co.; both shipped crude ore to a smelter.

Silver-lead ore, lead-copper ore, and copper ore shipped crude to a smelter comprised the output of the Little Cottonwood district in 1941.

The principal producers were the Wasatch Mines Co. and Columbus Rexall Consolidated Mines Co.

"Smelter" district.—The output from the "Smelter" district in 1941 came principally from the Mingo and Germania dumps and from clean-ups at the Utah Ore Sampling Co. yards and tracks.

West Mountain (Bingham) district.—The Bingham district, by far the outstanding mining region of Utah, produced most of the State output of copper and gold, nearly half of the zinc and lead, and more than a third of the silver in 1941; the value of these five metals was $82,558,340, or 84 percent of the value of the entire State output during the year. The following table gives the production from mines at Bingham in 1940 and 1941 and the total for the district from 1865 to 1941.

Mine production of gold, silver, copper, lead, and zinc in Bingham or West Mountain district, Salt Lake County, Utah, 1940–41, and total, 1865–1941, in terms of recovered metals

Year	Mines producing	Ore	Gold (lode and placer)	Silver (lode and placer)	Copper	Lead	Zinc	Total value
		Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*	
1940	14	26,753,382	256,558	4,760,252	457,010,531	75,713,100	43,623,397	$70,540,717
1941	15	30,866,163	275,119	4,851,872	529,409,000	69,024,000	40,991,000	82,558,340
Total, 1865–1941		(1)	4,470,927	121,990,525	[2] 3,425,919	[2] 1,420,362	[2] 392,245	1,367,736,039

[1] Figures not available.
[2] Short tons.

Utah Copper Co. operations accounted for most of the gain over 1940 in value of gold and silver produced and virtually all the gain in value of copper produced in the Bingham district in 1941. These gains in output were attained only through an all-out effort, started before 1941 and stimulated further by the present urgent need for copper. During 1941 the company milled an average of about 83,000 tons a day at its two flotation-concentration mills. The average copper content of the ore treated was slightly higher than in 1940, due chiefly to the fact that a larger portion of the ore came from the lower levels of the Bingham pit. Ore and waste were mined at a rate exceeding 188,000 tons a day. The waste rock was piled in adjacent gulches and leached there. In addition to the vast quantity of copper recovered from copper concentrates, the company recovered about 13,000,000 pounds of copper from the copper-precipitating plant at Lead Mine. The gold, silver, and molybdenite production from these copper ores far exceeded that of any other properties in the State, and the company ranked high among the leading gold and silver producers and second in production of molybdenite in the United States. In May 1942 the company exceeded its 1941 production schedule and was producing copper at the rate of about 600,000,000 pounds a year. The Kennecott Copper Corporation revealed the following operating details in its printed annual report. The mine operated 364 days during 1941, and the tonnage of ore hauled to the concentrators for treatment was 16 percent above that in 1940. The railroad congestion resulting from this larger tonnage

necessitated construction of a supplemental train-assembly yard about 1 mile from the main yard at Bingham.

The Boston Consolidated property, owned by the Utah Copper Co., was operated under lease by the American Smelting & Refining Co. Crude copper ore was shipped direct to a smelter.

The zinc and lead output of the Bingham district was produced largely by the United States & Lark mine, owned and operated by the United States Smelting, Refining & Mining Co. The tonnage of gold-silver ore and lead ore shipped for smelting increased slightly over the output in 1940, when 13,311 tons were shipped. The tonnage of zinc-lead ore shipped for milling at Midvale in 1941 was slightly less than in 1940 and lower in zinc and lead content but higher in gold and silver. In 1941 this property was second in silver and third in gold output in the State. During the first quarter of 1942, the property showed a marked increase in zinc-lead output over the monthly average for 1941. Development work consisted of driving 560 feet of shaft and 19,731 feet of raises. The Niagara mine shipped over 12,000 tons of ore of all classes to Midvale for treatment, and most of it was zinc-lead mill ore. The Montana-Bingham Consolidated Mining Co. shipped over 7,100 tons of ore of all classes. The Utah Metal property, leased by the United States Smelting, Refining & Mining Co., was the only other property active in the Bingham district in 1941 among those owned or controlled by the United States Smelting, Refining & Mining Co.; small shipments of zinc-lead ore were made incident to development of the property.

The National Tunnel & Mines Co. operated the Apex Delaware group from January through July 1941 on company and lessee account. The output was chiefly zinc-lead ore shipped to the Tooele sulfide concentrator and amounted to approximately one-half that produced in 1940. The Elton tunnel, driven by the National Tunnel & Mines Co., was completed in July 1941 as far as the main objective—reaching the Rood shaft in the Utah Apex mine. The rest of the year was spent mainly in rehabilitation of old workings and work preparatory to the extraction of ore. Limited production from the property was under way in April 1942; it is anticipated that by June 1942 normal production will have been established.

The Ohio Copper Co. treated 341,936 tons of old tailings, containing 2,097,531 pounds of copper in concentrates; in addition, 422 tons of copper precipitates were produced. The 1,000-ton flotation mill treated a daily average of 958 tons of tailings.

A total of over 31,000 tons of ore of all classes was shipped fom the Butterfield properties to the Combined Metals Reduction Co. concentrating plant at Bauer and to the International Smelting & Refining Co. at Tooele, or considerably less than the output in 1940.

Among other producers in the Bingham district in 1941 were the New England, Chicago, Kremlin, and Colonel Sellers properties, which shipped crude ore direct to smelters.

SEVIER COUNTY

Henry district.—Siliceous ore shipped crude to a smelter from the B. W. & H. property and from the Yellow Cougar No. 1–4 comprised the output from the Henry district in 1941.

Redmond district.—Zinc ore shipped crude to the Tooele slag-fuming plant was the only output from the Redmond district in 1941.

SUMMIT AND WASATCH COUNTIES

PARK CITY REGION

The Park City region includes the Uintah district in Summit County and the Blue Ledge and Snake Creek districts in Wasatch County. In 1941 the region produced gold, silver, copper, lead, and zinc valued at $7,798,348. The following table gives the output from the Park City region in 1940 and 1941 and the total since 1870.

Mine production of gold, silver, copper, lead, and zinc in Park City region, Summit and Wasatch Counties, Utah, 1940–41, and total 1870–1941, in terms of recovered metals

Year	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc	Total value
		Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*	
1940	12	311,906	17,300	3,333,122	1,296,000	39,497,400	35,195,000	$7,314,323
1941	12	337,595	19,747	3,271,199	1,507,000	38,188,000	32,353,000	7,798,348
Total, 1870–1941		(1)	473,385	226,668,134	63,327,513	2,287,946,834	585,052,911	336,879,568

1 Figures not available.

The Silver King mine and 800-ton flotation plant operated throughout 1941 and showed gains from 1940 in output of gold, silver, copper, and zinc but a decline in lead. The 800-ton flotation concentrator treated a daily average of 457 tons of zinc-lead ore, operating 5 days a week and three shifts a day. The gross metal content of the mill feed was virtually the same as in 1940, but no crude lead ore was shipped, as in the preceding year.

A total of 26,702 feet of development work was completed during 1941. According to the company printed annual report, the 116,443 tons of zinc-lead ore mined and milled produced lead, zinc, and iron concentrates that contained 1,855 ounces of gold, 1,173,437 ounces of silver, 598,953 pounds of copper, 15,732,531 pounds of lead, and 14,552,673 pounds of zinc. In addition, 1,092 tons of 62-percent zinc concentrates held in storage were sold.

The Park Utah Consolidated Mines Co. operated the Park Utah Consolidated Mines group in Summit County and the Keetley unit in Wasatch County continuously in 1941. All the ore was sent to the International smelter and mill for treatment. According to the company printed annual report, the 73,073 tons of ore produced contained 1,709 ounces of gold, 470,327 ounces of silver, 85,267 pounds of copper, 16,908,115 pounds of lead, and 15,716,159 pounds of zinc. Extensive development work was carried on at the property of the Park City Utah Mines Co. (affiliate of the Park Utah Consolidated Mines Co.) in Wasatch County. From the Park City Utah group the company produced 9,351 tons of ore of all classes, which was shipped to the International mill and smelter for treatment. In addition, the Park Utah Consolidated Mines Co. mined and shipped over 5,000 tons of zinc-lead ore, for the Daly Mining Co. from its Daly group, to the International smelter.

As part of its 1942 program, in view of the urgent need for base metals, the Park Utah Consolidated Mines Co. has reopened the orig-

inal main shaft at the Keetley unit, and extraction of the pillar of ore left around this shaft below the drainage-tunnel level has been begun. The additional tonnage from this section will bring an excess production over 1941 for the immediate future; but its tonnage is limited, and any excess production later in the year must necessarily come as a result of the favorable outcome of exploratory drives now in progress and those to be started in the near future. To increase the scope of the exploratory drives, the Anaconda Copper Mining Co. purchased a large share in the control of the company in April 1942.

The Park City Consolidated Mines Co. produced 45,998 tons of zinc-lead ore in 1941 from its Roosevelt and East Crescent groups and shipped it to the Midvale concentrator for treatment. The company produced about 70 percent as much ore as in 1940, but that mined and shipped in 1941 was of higher grade.

The New Park Mining Co. mined and shipped to the Midvale concentrator 58,600 tons of zinc-lead-copper ore, a gain of about 16,000 tons over 1940. The company was by far the leading gold producer in the region. In 1941 ore sent to Midvale for treatment contained 13,638 ounces of gold, 666,783 ounces of silver, 693,385 pounds of copper, 4,871,141 pounds of lead, and 4,978,013 pounds of zinc. A 2-mile railroad spur was constructed from Keetley to Cranmer, portal of the Mayflower tunnel; however, in 1941 all ore was hauled to Keetley for shipment. Development work was carried on continuously. Late in the year a shaft was started to permit exploring the levels below the Mayflower tunnel. Early in 1942 the mining crews were placed on a 7-day week and three-shift day. At the end of the first quarter of 1942, the company was producing at a rate that would exceed its 1941 output of all metals by a substantial margin.

The Marsac Mining Co., lessee on the Park Flag mine, operated the property for the first 6 months of 1941; at that time, the lease was transferred to D. C. Despain, and operations were continued for the rest of the year. About 3,400 tons of siliceous ore plus 800 tons of zinc-lead ore were shipped for treatment.

The remainder of the production from the Park City region came from shipments of zinc-lead ore and crude silver ore sent to smelters and mills, principally from the New Quincy property and from old tailings on Silver Creek and near Park City.

TOOELE COUNTY

Mines in Tooele County produced gold, silver, copper, lead, and zinc valued at $2,892,899 in 1941 compared with $3,747,433 in 1940. This decline in value of output was due chiefly to decreased output from mines in the Camp Floyd, Ophir, and Rush Valley districts, which more than offset the gain by the output of the Tooele slag-fuming plant.

Camp Floyd district.—Gold output in the Camp Floyd district decreased in 1941 compared with 1940. Snyder Mines, Inc., was again the largest producer in the district and treated over 168,000 tons of gold ore from company and custom shipments. The Geyser Marion Gold Mining Co. operated the Geyser Marion mill until the middle of June, when the mill was taken over by Snyder Mines, Inc. During the latter half of 1941, virtually all the gold output of the district was controlled by Snyder Mines, Inc. In addition to produc-

tion from the cyanide mills, about 40,000 tons of siliceous gold ore were shipped direct to Garfield for fluxing purposes. Active mines in the district included the Consolidated Mercur, New Mercur, La Cigale, Omaha, Sacramento, Geyser Marion, and Boston Sunshine.

Clifton (Gold Hill) district.—The Western Utah Copper property was the only producer in the Clifton district in 1941.

Dugway district.—Crude lead ore and zinc-lead ore were shipped direct to the International smelter and Bauer mills, respectively, for treatment from the Four Metals property, only active mine in the Dugway district in 1941.

Free Coinage district.—A small shipment of lead ore, sent direct to a smelter from the Utah Bunker Hill mine, was the only production from the Free Coinage district in 1941.

Lakeside district.—Lead ore shipped crude to a smelter from the Georgia Lyn, Lead Prince, and Monarch mines comprised the output from the Lakeside district in 1941.

North Tintic district.—The Scranton property was operated by lessees in 1941, and shipments of zinc ore and lead ore were made direct to the smelters.

Ophir district.—There was a sharp drop from 1940 in the metal output from the Ophir district in 1941, due chiefly to the decline in output from the Hidden Treasure mine, largest producer in the district. The property was operated by the United States Smelting, Refining & Mining Co. The tonnage of lead-copper ore shipped crude to the Midvale smelter was 3,000 tons less than in 1940; the production of zinc-lead-copper ore amounted to about 400 tons. The Ophir Development Co. operated the Ophir Coalition and Ophir Hill properties in 1941 and shipped to smelters 3,825 tons of ore of all classes. In addition, 1,675 tons of zinc-lead and zinc-lead-copper ores were shipped to the International sulfide concentrator. High-grade lead ore was shipped crude to a smelter by the Mecca Mining Co. (formerly the Cliff Lease) from the Wandering Jew. Among other mines active in the Ophir district were the Northern Light, Queen of the Hills, and the Mono group.

Rush Valley district.—The output from the Rush Valley district in 1941 declined from that in 1940. The West Calumet (Calumet) property, owned and operated by the Combined Metals Reduction Co., was by far the largest producer in the district in 1941. Over 38,000 tons of zinc-lead ore from the Calumet were treated at the Bauer plant, and in addition over 1,000 tons of crude ore were shipped direct to a smelter. Lead ore was shipped crude to the International smelter from the Bluestone mine in 1941. Other producers in the district included the Honerine, Salvation-Hercules, and Argenta.

"Smelter" district.—The International Smelting & Refining Co. erected a slag-fuming plant at the smelter location near Tooele. The plant was completed in September 1941 and during the rest of the year treated over 29,000 tons of zinc-lead slag and a few hundred tons of crude zinc ore. Zinc recovery averaged nearly 1,000,000 pounds a month during 1941. During the first quarter of 1942, the production had exceeded 1,000,000 pounds a month. The zinc fume produced averaged over 65 percent zinc and 2 percent lead and was shipped to the Anaconda Copper Mining Co. and to Bartlesville (Okla.) for treatment. The lead fume averaged about 45 percent lead and was treated at the Tooele lead smelter.

Willow Springs district.—The bulk of the output of the Willow Springs district came from rich gold ore and lead ore shipped crude to smelters from the Oro Del Rey and Depression mines.

UINTAH COUNTY

Most of the output from Uintah County was placer gold and silver recovered from the Big Bend, D. J. McConnell, and Utah State Lease No. 788 properties in the Green River district.

UTAH COUNTY

American Fork district.—The Dutchman mine was the largest producer in the American Fork district in 1941 and shipped 998 tons of high-grade zinc-lead ore to Midvale. Other mines active in 1941 included the Blue Rock, Bog Iron, Red Cloud, and Live Yankee.

Payson Canyon district.—A test lot of copper ore was shipped crude to a smelter from the Payson Canyon district.

Santaquin district.—One carload of lead ore was shipped crude to a smelter from the Elsie Jane mine in 1941.

Tintic district.—Mines in the Utah County section of the Tintic district are reviewed under Juab County.

WASHINGTON COUNTY

Gold ore amalgamated and a test shipment of silver ore sent direct to a smelter comprised the output from the Bull Valley district in 1941.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN WASHINGTON

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

Ores and gravels from mines in Washington yielded gold, silver, copper, lead, and zinc valued at $7,874,886 in 1941 compared with $7,018,812 in 1940. The output of each metal except copper increased. The gain in value of total output was due chiefly to greater production of lead and zinc, which was stimulated by the urgent need for these metals. Gold and silver production improved owing to a sharp rise in output from the Republic district, Ferry County, which more than balanced losses in the Methow district in Okanogan County and by the Howe Sound Co. in the Chelan Lake district, Chelan County. The bulk of the State copper production came from the Holden property of the Howe Sound Co. The decline from the 1940 output of copper can be ascribed to the lower grade of ore treated. The production of lead and zinc, which was derived chiefly from ores mined in Pend Oreille County, gained sharply over 1940 due principally to full-year operation of the properties of the Metaline Mining & Leasing Co. and the American Zinc, Lead & Smelting Co.; however, the Pend Oreille Mines & Metals Co. was the largest producer in the county. The productive effort of these three zinc and lead producers was greatly stimulated by defense requirements.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc. 1937–41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35 00	$0 7735	$0.121	$0 059	$0.065
1938	35 00	[4].646+	.098	.046	.048
1939	35.00	[5].678+	.104	.047	.052
1940	35.00	[6].711+	.113	.050	.063
1941	35 00	[6].711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] 1937. Yearly average weighted Treasury buying price for newly mined silver; 1938–41: Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787. [6] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Washington, 1937–41, and total, 1860–1941, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1937	65	90	294,826	36,310	$1,270,850	126,304	$97,696
1938	77	80	901,689	74,175	2,596,125	380,938	246,263
1939	88	84	1,124,564	90,420	3,164,700	442,063	300,067
1940	83	88	1,166,798	82,136	2,874,760	365,175	259,680
1941	61	56	1,238 509	84,176	2,946,160	402,030	285,888
1860–1941			(1)	1,881,725	44,615,698	11,222,890	7,941,147

[1] 1860–1903: Figures not available; 1904–41: 7,164,273 tons produced. [2] Short tons.

Gold and silver produced at placer mines in Washington, 1937–41, in terms of recovered metals

Year	Gold		Silver		Total value
	Fine ounces	Value	Fine ounces	Value	
1937	371	$12,985	48	$37	$13,022
1938	1,575	55,125	218	141	55,266
1939	2,261	79,135	358	243	79,378
1940	2,747	96,145	720	512	96,657
1941	540	18,900	90	64	18,964

Gold.—The output of recoverable gold in Washington was 84,176 fine ounces in 1941, a gain of 2 percent over 1940 due almost entirely to gold recovered from gold concentrates shipped to a smelter; gold recovered by amalgamation increased slightly but that recovered from gold cyanide bullion, copper concentrates, and crude ore shipped to smelters declined from 1940. Gold recovered from gold bullion from ore treated at cyanidation plants (with or without concentration) in Ferry County declined 6,131 ounces, but that in Stevens County gained 559 ounces; gold recovered from gold concentrates made in the concentration sections of the cyanide mills in Ferry County increased 18,299 ounces. Gold from ores sent crude to smelters was virtually the same as in 1940 in Ferry County but declined 1,856 ounces in Okanogan County and 198 ounces in Chelan County. Gold ores treated in amalgamation plants, principally from Ferry, Okanogan, and Whatcom Counties, yielded 777 ounces of gold. Copper concentrates produced by the Howe Sound Co. yielded about 55 percent of the State total and gold concentrates

produced from the Knob Hill and Mountain Lion groups 23 percent. Other important producers of gold were the Aurum and Valley mines in Ferry County and the First Thought mine in Stevens County. The total output of gold ore in 1941 was 178,121 tons compared with 202,502 tons in 1940; it was treated as follows: 135,290 tons cyanided, 694 tons amalgamated, 3,747 tons concentrated, and 38,390 tons sent crude to smelters. Placers yielded 540 fine ounces of gold in 1941.

Silver.—Recoverable silver produced in Washington in 1941 totaled 402,030 fine ounces, a gain of 10 percent over 1940; most of it came from copper ores of Chelan County and gold ores of Ferry County and the remainder chiefly from copper ores of Stevens and Snohomish Counties. Of the State total, copper ores yielded 50 percent, gold ore 43, silver ore 3, and the combined production of zinc-lead, gold-silver, and lead ores and placer gravels 4 percent. The Holden mine in Chelan County was the largest producer, followed by the Knob Hill and Mountain Lion properties in Ferry County, operated by Knob Hill Mines, Inc.; these two companies produced 75 percent of the State total. Other important silver-producing mines were the Aurum and Valley in Ferry County and the Amazon & Copper King in Stevens County. Placer mines yielded 90 fine ounces of silver.

Copper.—Recoverable copper produced in Washington amounted to 17,372,000 pounds in 1941 compared with 19,224,000 pounds in 1940. Copper concentrates shipped by the Howe Sound Co. from its Holden property to Tacoma yielded about 96 percent of the State total copper. The gold value in the copper concentrates was equivalent to 82 percent of the copper value. Other important copper producers were the Sunset mine in Snohomish County and the Amazon & Copper King and Lucky Boy mines in Stevens County.

Lead and zinc.—The production of recoverable lead and zinc in Washington in 1941 increased 53 and 24 percent, respectively, over that in 1940. Three properties in Pend Oreille County produced 98 percent of the State total lead and 99 percent of the zinc. Zinc-lead ore treated in two flotation mills in Pend Oreille County in 1941 exceeded that treated in 1940 by 87,808 tons and was virtually of the same grade. The 700-ton flotation mill of the Pend Oreille Mines & Metals Co. was operated the entire work year 7 days a week and three shifts a day. Ore treated daily averaged 661 tons. The 450-ton Grandview mill of the Metaline Mining & Leasing Co. treated company ore and ore from the property of the American Zinc, Lead & Smelting Co.; during 1941 the daily capacity of the mill was increased from 450 to 500 tons, and it was operated practically at capacity all of 1941 three shifts a day and 7 days a week. The Sierra Zinc Co., operating the Blue Ridge property in Stevens County, erected a 50-ton mill (50-ton flotation capacity and 100-ton crushing capacity) and began operations in October 1941. The average grade of ore treated was about 1 percent lead and 8 percent zinc. Other producers of lead included the Electric Point and Gladstone Mountain properties in Stevens County.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Washington in 1941, by counties, in terms of recovered metals

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

MINING INDUSTRY

Ore totaling 1,171,674 tons (95 percent of the State output) in 1941 was produced from six properties. This total includes copper ore from the Holden property in Chelan County; zinc-lead ore from the Pend Oreille, Metaline, and Grandview properties in Pend Oreille County; and gold ore from the Knob Hill and Mountain Lion properties in Ferry County. Development work on these six properties included 87,008 feet of diamond drilling and 4,826 feet of churn drilling; development work was also reported at several smaller properties in the State.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Washington in 1941, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	32	178,121	37,508	175,011	56,423	3,090	
Dry and siliceous gold-silver ore	5	87	32	1,216	380	1,900	
Dry and siliceous silver ore	8	2,492	53	10,723	1,234	1,322	
	45	180,700	37,593	186,950	58,043	6,312	
Copper ore	6	694,565	46,034	202,091	17,313,000		
Lead ore	3	152		360		112,830	
Zinc-lead ore	7	363,092	9	12,539	957	7,686,858	28,640,000
Total, lode mines	61	1,238,509	83,636	401,940	17,372,000	7,806,000	28,640,000
Total, placers	56		540	90			
	117	1,238,509	84,176	402,030	17,372,000	7,806,000	28,640,000
Total, 1940	171	1,166,798	82,136	365,175	19,224,000	5,110,000	23,120,000

METALLURGIC INDUSTRY

Lode mines in Washington produced 1,238,509 tons of ore in 1941, treated as follows: 1,063,076 tons in straight concentrating mills, 135,290 tons at cyanide plants, 694 tons at amalgamation plants, and 39,449 tons shipped crude to smelters.

Amalgamation plants.—Ten straight amalgamation plants and one amalgamation and concentration plant treated 694 tons of dry gold ore in 1941. The Boundary Red Mountain property in Whatcom County was the chief producer.

Cyanidation mills.—The 400-ton cyanidation-concentration plant of Knob Hill Mines, Inc., at Republic, Ferry County, treated the bulk of the gold ore cyanided in 1941; the plant treated gold ore from the Knob Hill and Mountain Lion mines. The First Thought Mine Corporation treated gold ore from the First Thought mine in the Orient district, Stevens County, in its 50-ton plant. These two mills treated a total of 105,218 tons of gold ore and reported the consumption of 7,675 pounds of sodium cyanide (91-percent grade), 163,800 pounds of calcium cyanide, 29,500 pounds of zinc dust, and 1,371,800 pounds of lime.

Concentration mills.—A total of 1,063,076 tons of ore was treated at 13 flotation mills, as follows: 693,937 tons of copper ore treated at 4 plants, 363,092 tons of zinc-lead ore at 4 plants, 3,747 tons of gold ore at 4 plants, and 2,300 tons of silver ore at 1 plant.

Details of the treatment of all ore produced in Washington in 1941 are given in the following tables.

Mine production of metals in Washington in 1941, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated	694	777	363			
Ore cyanided	135,290	6,582	16,996

Comment on districts with small output has been omitted owing to lack of space.

ASOTIN COUNTY

Most of the output of gold from Asotin County in 1941 came from the operations of three small dragline and washer plants on Snake River.

BENTON COUNTY

The Benton County output in 1941 was derived from several small sluicing operations and one dragline working placers along the Columbia River near Paterson and Richland.

CHELAN COUNTY

Chelan Lake district.—The Holden property of the Howe Sound Co. was again the leading producer of gold, silver, and copper in Washington. Although the ore milled totaled 687,343 tons in 1941—almost equal to the 687,429 tons milled in 1940—the output of metals declined because a lower grade of ore was treated. In 1941 the grade of ore averaged 0.08 ounce of gold and 0.310 ounce of silver to the ton, 1.30 percent copper, and 0.88 percent zinc. The copper concentrates produced averaged about 1.30 ounces of gold and 5 ounces of silver to the ton and 24 percent copper. Mine development included sinking 150 feet of vertical and 377 feet of inclined shaft and driving 14,263 feet of drifts and 2,605 feet of raises, besides 44,139 feet of diamond drilling. The 2,000-ton company concentrator operated continuously in 1941 at slightly above rated capacity; a cyanide plant that was to start operations in January 1942 was added to the concentrator.

Peshastin Creek District.—Several small lots of crude gold ore were shipped to smelters in 1941, chiefly from the Old Blewett and Polepick mines.

DOUGLAS COUNTY

Gold recovered from bars along Columbia River by sluicing was the entire metal output of Douglas County in 1941.

FERRY COUNTY

Danville district.—Production of gold at the Morning Star mine from ore shipped to smelters and ore amalgamated increased in 1941.

Enterprise district.—A small amount of crude silver ore from the Silver Bell property was shipped to Tacoma for smelting in 1941.

Republic district.—The entire output of gold, silver, and copper in 1941 came from siliceous gold ore; 123,290 tons were treated by cyanidation and 10 tons by amalgamation, and 37,179 tons were shipped crude to a smelter. All the ore from the Knob Hill and Mountain Lion groups, operated by Knob Hill Mines, Inc., was treated in the 400-ton cyanide-flotation plant at the Knob Hill mine, producing 3,590 tons of gold concentrates in addition to cyanide bullion. Most of the crude ore from the Republic district, shipped for smelting, came from company and leasing operations on properties of the Aurum Mining Co. Other important shippers of crude ore were Golden Valley, Inc., operating the Valley claim; the Eureka

Mining & Milling Co., operating its Blaine-Republic properties on company and leasing accounts; Flag Hill Mines, operating the Scalawag mine; and operators of the South Penn property. A small amount of placer gold was recovered by sluicing on Columbia River.

GRANT COUNTY

All gold produced in Grant County during 1941 was recovered by the dry-land dredge operated by Miller Bros. at Chinaman Bar on Columbia River.

KING COUNTY

Most of the gold from King County in 1941 was contained in gold concentrates produced from gold ore treated in the 75-ton flotation mill at the Apex property. Small lots of siliceous gold-silver and siliceous silver ores were shipped from the Coney Basin and Cleopatra properties, respectively, for smelting.

KITTITAS COUNTY

Swauk district.—Several small sluicing operations produced placer gold from Swauk Creek in 1941.

Yakima River district.—A small amount of placer gold was recovered by sluicing on Yakima River.

OKANOGAN COUNTY

Cascade district.—The Bodie group near Wauconda, treating gold ore by amalgamation and concentration, produced the entire output of the Cascade district in 1941.

Loomis-Oroville district.—Two small lots, one of gold ore and the other of gold-silver ore, comprised the output of the Loomis-Oroville district in 1941.

Methow district.—The Methow Gold Corporation treated ore by amalgamation in the 40-ton Red Shirt mill and was the leading producer in the Methow district in 1941. Other producers were the New London, Highland Light & Hidden Treasure, Gold Crown, Minnie, and Gold Coin properties.

Myers Creek and Mary Ann Creek district.—Gold ore from the Mother Lode property represented the bulk of the output in 1941.

PEND OREILLE COUNTY

Metaline district.—The Pend Oreille County metal output increased in value from $1,712,157 in 1940 to $2,573,300 in 1941, owing chiefly to greater output of lead and zinc. The Pend Oreille Mines & Metals Co. operated the Josephine group the entire year and milled an average of 661 tons of ore a day in its 700-ton flotation mill. The company produced about 56 percent of the zinc and about 49 percent of the lead output of the Metaline district. The average content of the zinc-lead ore milled in 1941 was about 1 percent lead and 5 percent zinc. Development work reported by the company totaled 500 feet of incline, 1,701 feet of drifts, 485 feet of raises, and 18,067 feet of diamond drilling. The remainder of the zinc and lead output of the district was contained in zinc and lead concentrates produced by the 450- to

500-ton Grandview flotation mill, which treated ore from properties of the Metaline Mining & Leasing Co. and the American Zinc, Lead & Smelting Co. The crushing and classifier sections of the Grandview mill were enlarged, thereby increasing the milling capacity from 450 tons a day to 500 tons. Placer gravels yielded a small amount of gold.

PIERCE COUNTY

A small lot of gold ore was shipped crude to Tacoma in 1941 from the Silver Creek property in the Mount Rainier district.

SNOHOMISH COUNTY

Index district.—The Sunset Cooperative Mining Co. shipped copper concentrates and some crude ore to Tacoma for smelting in 1941, surpassing its 1940 production by more than 60 percent. The company operated its 150-ton flotation mill until November, when the Kromona Mines Corporation assumed control of the property.

Stilaguamish district.—Silver concentrates were shipped to Tacoma in 1941 for smelting, from properties operated by the Ore Recoveries Corporation at Silverton.

Sultan district.—The Kromona Mines Corporation operated the Florence Rae property in 1941 and shipped crude copper ore to Tacoma for smelting. A small amount of placer gold was recovered by sluicing along Sultan River.

STEVENS COUNTY

Bossburg district.—Small lots of zinc-lead ore, from the Silver Trail and Young America mines, treated in the Budd custom mill at Kettle Falls (Kettle Falls district) comprised the output of the Bossburg district in 1941. The Budd mill, owned by Ark Mines, is a 40-ton flotation mill.

Chewelah district.—The Chinto Mining Co., treating ore from company properties, in its 25-ton flotation mill, produced copper concentrates that yielded the metal output of the Chewelah district in 1941.

Columbia River district.—The Columbia River district of Stevens County was the largest producer of placer gold in the State in 1941. The bulk of the gold was recovered from properties along Columbia River operated by R. H. Fish and the Harvey R. Cline Co., both using mechanical equipment.

Colville district.—A small lot of zinc-lead ore from the Smokey Bullion mine was treated in the Budd custom mill and yielded the entire metal output of the Colville district in 1941.

Deer Trail district.—Several small lots of silver-lead ore were shipped crude to a smelter in 1941.

Northport district.—The Sierra Zinc Co. started production at the Blue Ridge mine in October 1941 and produced the bulk of the 1941 metal output of the Northport district. The company erected a 50-ton mill (crushing capacity, 100 tons) on the property in 1941. The remainder of the district output consisted of lead ore shipped crude to a smelter from the Electric Point and Gladstone Mountain mines and a small lot of silver ore from the Frisco-Standard mine.

497779—43——33

Orient district.—The First Thought Mine Corporation treated about 12,000 tons of siliceous gold ore in its 50-ton cyanidation mill and produced the bulk of the metal output of the Orient district in 1941.

Springdale district.—Ore from the Lucky Boy mine (only producer in the Springdale district in 1941) was treated in the Deer Trail 100-ton flotation mill and yielded copper concentrates; in addition, a small lot of ore was shipped crude to Tacoma.

WHATCOM COUNTY

Mount Baker district.—Ore from the Boundary Red Mountain mine, treated by amalgamation, contained most of the gold produced in the Mount Baker district in 1941.

Slate Creek district.—The bulk of the Slate Creek district output came from gold ore shipped crude to Tacoma from the Azurite property and from gold concentrates produced by the Slate Creek Mining Co. in its 75-ton flotation mill. A little gold was recovered from placers on Slate Creek by sluicing.

WHITMAN COUNTY

Snake River district.—A few ounces of gold were recovered from the Indian Bar placer on Snake River by sluicing.

YAKIMA COUNTY

Summit district.—A small lot of copper ore was shipped crude to Tacoma from the Chinook mine.

GOLD, SILVER, COPPER, AND LEAD IN WYOMING

(MINE REPORT)

By CHAS. W. HENDERSON AND S. A. GUSTAVSON

SUMMARY OUTLINE

Lode and placer mines in Wyoming in 1941 yielded—in terms of recovered metals—478 fine ounces of gold, 94 fine ounces of silver, and 8,000 pounds of copper. Of this total, 447 ounces of gold and 50 ounces of silver were recovered from placer mining, the bulk of it by two dry-land dredge operations in the Atlantic City district of Fremont County; small hand-sluicing or panning operations—one in Albany County, two in Carbon County, and seven in Fremont County—supplied the remaining placer output.

No large lode-mining operations were carried on in the State to recover gold, silver, copper, or lead in 1941. Eight small lode mines, none of which shipped or treated over 40 tons of crude ore, yielded—in terms of recovered metals—31 fine ounces of gold, 44 fine ounces of silver, and 8,000 pounds of copper. A total of 75 tons of crude ore was treated in four small amalgamation mills—three in Fremont County and one in Johnson County—which recovered 10 fine ounces of gold and 4 fine ounces of silver. A total of 42 tons of copper ore and 42 tons of dry gold ore from three mines in Carbon County and one mine in Platte County (yielding 21 fine ounces of gold, 40 fine ounces of silver, and 8,000 pounds of copper) was shipped to the Garfield (Utah) smelter.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1937-41

Year	Gold [1]	Silver [2]	Copper [3]	Lead [3]	Zinc [3]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1937	$35.00	$0.7735	$0.121	$0.059	$0.065
1938	35.00	[4] .646+	.098	.046	.048
1939	35.00	[5] .678+	.104	.047	.052
1940	35.00	[6] .711+	.113	.050	.063
1941	35.00	[6] .711+	.118	.057	.075

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+ ($20.671835) per fine ounce.
[2] 1937: Yearly average weighted Treasury buying price for newly mined silver, 1938-41 Treasury buying price for newly mined silver.
[3] Yearly average weighted price of all grades of primary metal sold by producers.
[4] $0.64646464. [5] $0.67878787 [6] $0.71111111

The following table shows the annual output of ore from lode mines producing gold, silver, copper, and lead and the quantity and value of the metals recovered from both lode and placer mines in Wyoming from 1937 to 1941; it also gives the total production of metals from 1867 to 1941. About three-fourths of the total recorded value of the four metals is in copper, most of which was mined before 1924 in the Encampment district, in Carbon County, and the Hartville district, originally in Laramie County, now in Platte County.

Mine production of gold, silver, copper, and lead in Wyoming, 1937–41, and total, 1867–1941, in terms of recovered metals

Year	Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)		Copper		Lead		Total value
		Fine ounces	Value	Fine ounces	Value	Pounds	Value	Pounds	Value	
1937	17	1,776	$62,160	203	$157					$62,317
1938	581	798	27,930	328	212					28,142
1939	57	583	20,405	75	51					20,456
1940	813	740	25,900	114	81	4,000	$452			26,433

REVIEW BY COUNTIES AND DISTRICTS

ALBANY COUNTY

Centennial district.—The only mining operations in the Centennial district in 1941 were those incident to development or assessment work.

Douglas Creek district (Holmes, Keystone).—A small lot of placer gold was recovered by Ira J. Knisley on the west branch of Little Beaver Creek. Development and assessment work were the only other mining operations carried on in the Douglas Creek district. Pete Erickson, of Holmes, did development work on the Lucky Strike property. The Multi Metals Corporation also did development work and made tests for the treatment of ore from its Gold Crater group of claims near Keystone.

BIG HORN COUNTY

There was no metal production from Big Horn County in 1941. Some sampling for gold of bench gravel on the Big Horn River, about 7 miles north of Kane, was done by George E. Frame.

CARBON COUNTY

Elkhorn Mountains district.—Assessment work and some sampling were done by the Golden Sun Mining Syndicate on the Vulcan group of claims; a small shipment of gold ore was sent to the Garfield (Utah) smelter of the American Smelting & Refining Co. Shull, Johnson & Hoggard made a small shipment of copper ore to the Garfield smelter. Development work was carried on at the Silent Six group by C. H. Ashley, of Encampment, and at the Hub group by Joe McCarthy, of Livermore, Colo.

Encampment or Upper Platte district.—The Golden Clover claim was developed further, and a few tons of dry gold ore were shipped to the Garfield (Utah) smelter.

Savery Creek district.—Sluicing of about 700 cubic yards of gravel in Savery Creek by John Malten yielded 2½ ounces of gold.

FREMONT COUNTY

Atlantic City district.—The holdings of Crawford Bros., including the complete dry-land washing plant and all leases of the E. T. Fisher Co., were purchased in November 1940 by C. E. Gish of Farnam, Nebr. Gish operated the plant in 1941 and treated about 80,000 cubic yards of gravel, from which 224 fine ounces of gold and 26 fine ounces of silver were recovered; the average fineness of the bullion was 0.890 in gold and 0.105 in silver, the same as in 1940. The placering was carried on chiefly on the Timba-Bah Mining Co. property about 5 miles below Atlantic City, largest single producer of gold and silver in the State in 1941. John E. Whisenand's placer operation on Sweetwater River in the vicinity of Atlantic City, worked by a 3-cubic yard dragline and a washing plant, ranked second in output of gold and silver. His bullion had an average fineness of 0.894 in gold and 0.083 in silver. The plant was shut down and moved to Farson, Wyo., in the fall of 1941. There were small hand-operated placers in Big Atlantic Gulch, Meadow Gulch, and Rock Creek.

Roy A. Cowden, of Atlantic City, operated the Gold Leaf and Mint lode-mining claims and treated 40 tons of ore in a 5-ton Gibson amalgamation mill, producing 5½ ounces of gold bullion which was sold to the Denver Mint. Jacob Stevenson and J. C. Gibson operated the Caribou mine, did development work, and treated 10 tons of ore. J. Don Birch operated the St. Louis mine and the Birch 10-ton amalgamation mill; 10 tons of ore were treated and yielded 2.84 ounces of fine gold and 0.48 ounce of fine silver.

Copper Mountain district.—Using a portable mechanical placer machine, H. B. Crawford in sampling and testing placer ground handled 30 tons of old tailings and stream gravel in Birdseye Creek below the Gold Nugget mine on Copper Mountain; about 1 ounce of fine gold was recovered.

JOHNSON COUNTY

The Powder River Mining Corporation treated a few tons of ore from the Powder River mine. The property is in sec. 20, T. 47 N., R. 85 W.

PLATTE COUNTY

Oscar Alexander made a shipment of 3 tons of copper ore to the Garfield (Utah) smelter. The Colorado Fuel & Iron Co. produced no copper ore at its Sunrise iron mine in 1941.

TETON COUNTY

Some sampling work was done on the Mercury placer on Snake River about 7 miles southeast of Moran, but no product was marketed.

SECONDARY METALS—NONFERROUS

By F. H. Wright and J. H. Schaum [1]

SUMMARY OUTLINE

GENERAL SUMMARY

All previous records for annual recovery of secondary nonferrous metals were broken in 1941. The value of economically important nonferrous metals recovered from scrap, as metal and in alloys and chemicals, totaled $348,377,389 in 1941 compared with $242,789,445 (revised) in 1940. Metals recovered from new scrap that entered the market as a byproduct of manufacturing operations comprised $143,114,982 of the total, and metals recovered from old and obsolete salvage materials were valued at $205,262,407.

Salient statistics of nonferrous secondary metals recovered in the United States, 1940–41

Metal	New scrap		Old scrap		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1940						
Aluminum	[1] 34,556	[1] $12,612,940	[1] 45,806	[1] $16,719,190	[1] 80,362	[1] $29,332,130
Antimony	245	68,600	11,176	3,129,280	11,421	3,197,880

[1] Revised figures. [2] Data not available.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce

Although the full effect of all-out war production was not felt in the secondary metals industry during 1941, there were many instances of change. Turnings and clippings of aluminum, magnesium, copper, and brass were produced in tremendous quantities but for the most part were routed back to rolling mills. Denial of export licenses for nickel scrap created the need for recovery facilities in the United States, and several plants expanded their operations.

The better grades of all scrap metals were always in demand during 1941, but some of the lower grades suffered because they could not be used in products that had to meet the rigid specifications of armament production. Unalloyed copper scrap and high-tin bronze supplies fell far short of requirements. It is interesting to note that more of almost every type of scrap was consumed in 1941 than in 1940.

Aluminum and zinc scrap held the spotlight in January and February, with many instances of scrap prices far above those of primary metal, owing to surging business activity and a demand exceeding primary production facilities. Both aluminum and zinc scrap virtually disappeared from the market when the first official scrap price ceilings were imposed in March, and normal flow was not resumed until midsummer.

Smelters and ingot makers experienced difficulty in finding sufficient copper, brass, and bronze scrap during most of 1941, but they had less trouble after a large part of the competition from foundries was removed by priority control in October. Even though some dealers had difficulty in disposing of low-copper-bearing materials, consumption of copper-bearing scrap and residues was almost four times that of 1940.

Most nonferrous scrap-metal prices averaged 1 cent to 1.8 cents a pound higher in 1941 than in 1940.

SCOPE OF REPORT

New features were added to the canvass of nonferrous scrap-metal consumers in 1941. Remelters, smelters, and refiners were asked to report the weight and composition of metals and alloys produced from scrap, and manufacturers and foundries, including brass mills, aluminum rolling mills, and chemical works, were asked to list their products and report the secondary metal contents.

Secondary magnesium rose to a position of economic importance during 1941 and is reported in this chapter for the first time.

In all, 344 plants were classified as remelters, smelters, or refiners of nonferrous scrap metals in 1941. Some of these plants specialized in one base metal, whereas others combined a variety of functions and consumed many types of scrap.

Consumption of purchased nonferrous scrap metals was reported by 1,192 manufacturers and foundries (including brass mills and chemical works) in 1941. Many foundries and manufacturers made their initial entry into the scrap market in 1941 in search of materials to fill rated orders, and other consumers who used scrap during the first half of the year were unable to obtain priorities for further purchases.

Each table of secondary metals recovered shows the total quantity of each element reclaimed directly as metal or in chemical compounds and, in addition, the quantity of that element reclaimed in alloys recovered from certain types of alloy scrap. The fact that a metal

is recovered in one type of alloy scrap does not necessarily mean that the final product was an alloy of the same class. For example, tin recovered in solder (a lead alloy) might emerge from the plant as an alloying element in bronze ingot. From the foregoing it is obvious that there is no basis for direct comparison between the tables of metal "recovered" and the tables of metal products, introduced in this chapter for the first time.

SECONDARY ALUMINUM

The quantity of secondary[2] aluminum recovered from scrap totaled 106,857 short tons valued at $34,707,153 in 1941 compared with 80,362 tons valued at $29,332,130 in 1940 (revised figures). The value was computed at 16.24 cents a pound of weight recovered in 1941 compared with 18.25 cents in 1940.

Secondary aluminum recovered in the United States, 1940–41, in short tons

	1940 [1]	1941
As metal	5,620	8,308
Aluminum alloys produced and recovered from aluminum scrap	74,742	97,614
In chemical products:		
Aluminum chloride	(2)	784
Aluminum sulfate	(2)	151
	80,362	106,857
From new scrap	34,556	63,744
From old scrap	45,806	43,113

[1] Revised figures. [2] Data not available.

The 8,308 tons of secondary aluminum recovered as metal appeared on the market as 3,449 tons of pure aluminum (98.5 percent) ingot, 1,663 tons of aluminum powder, 931 tons of pure aluminum castings, and 2,265 tons in commercial shapes produced by rolling mills.

The 97,614 tons of secondary aluminum alloys recovered from aluminum scrap appeared in such products as aluminum-alloy ingot, alloy castings, zinc-base die-cast alloys, and aluminum bronze.

Production of secondary aluminum [1] and aluminum-alloy products in the United States, 1940–41, gross weight, short tons

	1940	1941
Secondary aluminum ingot [2]		
Pure aluminum (98.5 percent)	4,679	3,449
95.5 (silicon)	5,679	4,014
Other aluminum-silicon alloys	1,539	3,356
No. 12 aluminum	17,519	21,708
Other aluminum-copper alloys	1,613	6,477
Aluminum-copper-silicon alloys	12,334	10,113
Steel-mill ingot and shot	19,427	24,212
Die-casting alloys	2,552	4,431
Aluminum hardeners	1,340	4,747
Miscellaneous	1,807	1,426
	68,489	83,933
Aluminum powder	(3)	1,663
Aluminum castings	(3)	9,851
Aluminum in chemical products	(3)	935

[1] In addition to the secondary aluminum produced, 670 tons of aluminum were recovered from aluminum scrap in zinc die-casting alloys, and 291 tons in aluminum bronze; 14,221 tons were combined with primary aluminum in the products of aluminum rolling mills.
[2] Gross weight of alloys, including copper, silicon, and other added elements; total secondary ingot contained 3,718 tons of primary aluminum in 1940 and 1,038 tons in 1941.
[3] Data not available.

[2] The term "secondary aluminum" is used in the broad sense covering aluminum and aluminum alloys, including the weight of alloy constituents, such as copper, silicon, magnesium, etc.

Thirteen chemical-producing companies recovered 784 tons of aluminum in aluminum chloride and 151 tons in aluminum sulfate. The second half-year activity in chemical production approximately doubled that of the first half.

Despite an erratic production rate, 80 secondary ingot makers produced 83,933 tons of various grades of ingot, resulting in a 23-percent increase over the 1940 output, which was still far below the maximum capacity available.

The average monthly production of secondary ingot was 6,994 tons. Monthly output rose from about 8,000 tons in January and February to almost 10,000 tons in March, then fell abruptly to 4,500 tons in May, when dealers withdrew from the market after price ceilings had been set. Production became stabilized toward the end of 1941 as confidence returned to the trade.

New scrap from the fabrication of aluminum sheet and forgings was largely routed back to aluminum rolling mills for most efficient recovery of the low-alloy metal consumed in aircraft production. In 1941, 14,221 short tons of aluminum were thus recovered from scrap by working the metal in with primary aluminum.

The quantity of aluminum recovered from old scrap in 1941 was slightly less than recovery from old scrap in 1940, but recovery from new scrap increased 84 percent.

Consumption of purchased aluminum scrap in the United States in 1941, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries				Total scrap used
			Aluminum rolling mills		Foundries and other manufacturers		
	New scrap	Old scrap	New scrap	Old scrap	New scrap	Old scrap	
Pure clippings, wire, and foil	2,565	1,083	3,184	16	869	849	8,566
Castings and forgings	4,320	23,401	28		223	5,466	33,438
Alloy sheet	9,365	1,447	625	3	1,331	68	12,839
Scrap sheet and sheet utensil	1,050	11,734	10,510	78	103	888	24,363
Borings and turnings	30,618		1,379		594		32,591
Die castings		169			34	38	241
Miscellaneous aluminum and dross	13,732	81	71		517	8	14,409
	61,650	37,915	15,797	97	3,671	7,317	126,447

The consumption of 126,447 tons of aluminum scrap in 1941 represents a 36-percent increase over 1940. About 79 percent of the scrap was used by 99 remelters, smelters, and refiners; 13 percent by 14 aluminum rolling mills; and the remaining 8 percent by 997 foundries and miscellaneous manufacturers.

Of the total aluminum scrap used in 1941, Ohio consumed 33 percent, Illinois 21 percent, Michigan 9 percent, New York 7 percent, California 6 percent, Pennsylvania 6 percent, Tennessee 5 percent, and all other States 13 percent.

As the sources of old scrap were depleted to some extent, the market in 1941 reflected its increased dependence on new scrap generated by manufacturers, and 64 percent of all scrap consumed was new. In 1940, new scrap constituted only 43 percent of the total

Remelters, smelters, and refiners proved the largest consuming group by taking 99,565 tons of aluminum scrap, a 29-percent rise over 1940. Although die castings, pure clippings, wire, and foil all revealed diminished usage, the 30,618 tons of borings and turnings consumed amounted to almost double the 1940 consumption. Virtually all of the scrap used by aluminum rolling mills was new scrap that was a byproduct of industrial fabrication. Foundries and miscellaneous manufacturers consumed only 10,988 tons of aluminum scrap, slightly less than in 1940. Early in 1942, an order was issued making it mandatory for all companies whose operations yielded more than 1,000 pounds of aluminum scrap a month to segregate all scrap produced.

Consumers' stocks of purchased aluminum-base scrap in the United States at end of year, 1940–41, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1940 [1]	Dec. 31, 1941
Castings and forgings	2,734	2,004
Sheet, turnings, clippings, etc.	3,690	6,070
Miscellaneous aluminum and dross	1,802	1,521
	8,226	9,595

[1] Revised figures.

The base price of primary aluminum ingot was reduced from 17 cents a pound to 15 cents a pound in October and averaged 16.50 cents for the year. The average price for the 98 percent pure secondary aluminum was about 17.36 cents.

Dealers' buying prices for scrap cast aluminum in New York averaged 10.76 cents a pound in 1941 compared with 8.95 cents in 1940. Prices averaged 13.97 cents in February, but March prices could not be averaged for lack of quotations. Following the announcement of official ceiling prices on March 25, the monthly average dropped to 11.00 cents in April and remained static until October, when an average of 9.36 cents a pound reflected the drop in price of both primary metal and scrap. Cast scrap averaged 9.37 cents in December.

Dealers' buying prices for new aluminum clippings in New York averaged 13.00 cents a pound in 1941 compared with 14.47 cents in 1940. From a peak of 16.88 cents averaged in March, the price dropped to the ceiling level of 13.00 cents, eased to 11.36 cents a pound in October, and ended the year with a December average of 9.37 cents.

Effective March 25, 1941, a dual price ceiling listing maximum prices for sale of aluminum scrap by maker, as well as for sale to consumer, was announced by the Office of Price Administration. Secondary ingot (98 percent pure) was fixed at 17 cents a pound, and scrap prices were set in relation to the prevailing rate for primary metal (17 cents a pound). The flow of aluminum scrap immediately dried up and did not resume normal volume until late in the summer of 1941.

Many secondary aluminum-ingot makers were shut down in April and May, and a few operated at reduced schedules. Nevertheless, ingot production during the first half of 1941 advanced 21 percent over the half-year rate in 1940.

On November 1, 1941, scrap-aluminum price ceilings were reduced to conform with the new 15-cent base price of primary metal, and the dual price schedule was abolished in favor of a single list of maximum sale prices. Secondary ingot was also reduced to 15 cents for 98-percent metal.

Aluminum scrap was placed under full priority control on June 10, 1941, but smelters did not receive an A-10 rating until the first of July.

The much publicized house-to-house aluminum-collection campaign in July netted 5,600 short tons of mixed scrap metals containing about 3,200 tons of recoverable aluminum.

Imports of aluminum scrap into the United States were only 26 tons for the first 9 months of 1941 compared with 648 tons in all of 1940. No figures on exports were available for publication.

SECONDARY ANTIMONY

A total of 21,629 short tons of secondary antimony valued at $6,056,120 was recovered in 1941 compared with 11,421 tons valued at $3,197,880 in 1940. The value in both years was computed at 14 cents a pound, the average price for ordinary brands of American-grade antimony. The expanded recovery of antimony represented an increase of almost 90 percent over 1940.

Secondary antimony recovered in the United States, 1940–41, in short tons

	1940	1941
In lead-base alloys [1]	11,073	21,337
In tin-base alloys	348	292
	11,421	21,629
From new scrap	245	57
From old scrap	11,176	21,572

[1] Includes antimony recovered as metal and in oxide and other compounds. 867 tons of antimony were recovered in antimonial lead produced at primary lead refineries in 1940 and 532 tons in 1941

The rise in secondary antimony was entirely attributable to the 21,337 tons recovered in lead-base alloys. There was a 16-percent decline in antimony recovered in tin-base alloys—from 348 tons in 1940 to 292 tons in 1941. Nearly all of the antimony was recovered in old scrap. Only 2,113 tons (10 percent of the total) were recovered by consumers classified as manufacturers and foundries.

A table of the secondary lead and tin-base alloy products containing secondary antimony may be found in the section on Secondary Lead. Antimonial lead products yielded 77 percent of the secondary antimony recovered, including 10,820 tons contained in high antimonial lead (over 8 percent antimony). This latter type of antimonial lead is produced largely in conjunction with the recovery of refined lead from battery plates, when antimony slag is smelted to make a hard lead containing up to 16 percent antimony. The 21,629 tons of secondary antimony reported in 1941 were recovered in 371,809 tons of lead-base scrap and 4,725 tons of tin-base scrap. Battery-lead plates were the source of almost 60 percent of the total secondary antimony, and the remainder was supplied by type metal and type dross, hard lead, and bearing metals. The threatened

shortage of lead resulting from unusually heavy demand brought out large amounts of old battery plates.

Consumption of purchased antimony-bearing scrap in the United States in 1941 gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Lead-base scrap.					
Hard lead	539	37,693	117	234	38,583

1 Less than 1 ton.

On January 13, 1942, the maximum price allowed for the antimony content of secondary antimonial lead was set at 14 cents a pound, but the factor was advanced to 15.50 cents a pound on March 31, 1942. The War Production Board placed antimony under full priority control, effective May 1, 1942.

SECONDARY COPPER AND BRASS

More than 1,000,000 short tons of purchased [3] copper and copper-base scrap were consumed in 1941. Copper recovered from scrap metals, including that in alloys, totaled 726,396 short tons valued at $171,429,456 in 1941 compared with 532,046 tons valued at $120,242,396 in 1940. The value was computed at 11.8 cents a pound in 1941, whereas the average price of 11.3 cents was used in 1940.

In all, 135,869 tons of copper were recovered in 1941 as essentially pure metal, most of which was refined electrolytically. Of the total copper recovered in copper-alloy products, yellow brass alloys contributed 234,191 tons (copper content), and alloys other than yellow brass supplied 346,532 tons of secondary copper. In addition to copper recovered as metal and in alloys, 9,804 tons were recovered from scrap metals in the form of chemicals.

Owing to greatly increased demand for clean copper scrap at foundries and secondary brass-ingot plants, recovery of refined copper from scrap at primary copper refineries decreased 15 percent from 117,669 short tons in 1940 to 99,675 tons in 1941.

3 The term "purchased scrap" includes scrap treated on toll as well as scrap transferred between plants of a single company It does not include home scrap reused in the plant in which it originated

Secondary copper recovered in the United States, 1940–41, in short tons

	1940	1941
As metal	170,839	135,869
In brass and other alloys	361,207	590,527

Copper in chemical products (copper content)							9,804

[1] Gross weight of secondary brass and bronze in commercial shapes; includes 221,492 tons of copper, 1,200 tons of nickel, 4,166 tons of lead, 236 tons of tin, and 81,313 tons of zinc.

[2] Gross weight of secondary brass and bronze castings, includes 123,955 tons of copper, 1,424 tons of nickel, 9,087 tons of lead, 6,986 tons of tin, and 11,185 tons of zinc

As would be expected with expanded production of munitions added to a general upswing in manufacturing activity, secondary copper and copper in alloys recovered from new scrap in 1941 increased 58 percent over the 1940 figure. The 24-percent increase in recovery of copper in old scrap reflected the consumption of reserves of old copper and brass scrap brought out by an active market,

augmented by scrap-collection campaigns. Unalloyed copper scrap yielded 231,500 tons of secondary copper, which was recovered partly as refined metal, to a limited extent in copper chemical products, and to a greater extent in brass and bronze. Of this amount, 59,078 tons came from new unalloyed copper scrap and 172,426 tons from old unalloyed scrap.

No direct comparison may be made between the table of secondary copper "recovered" and the table of copper products. The tabulation of metal "recovered" includes copper contained in nickel-base, aluminum-base, and tin-base alloy scrap, as well as the copper recovered by direct addition of copper scrap to such items as secondary aluminum ingot or tin babbitts. The tabulation of copper and copper-alloy products lists the gross weight of secondary copper alloys, including both primary and secondary tin, lead, zinc, nickel, aluminum, and a small quantity of primary copper.

Refined electrolytic-grade copper was produced at 12 refineries, including 10 primary plants. Of the 109,368 tons of refined copper produced, 83 percent was supplied by 5 plants. Casting copper was produced at 21 plants, of which only 1 was a primary copper refinery.

Secondary brass and bronze ingots totaling 299,021 short tons were produced by 78 ingot-manufacturing plants representing 65 companies. Stocks of secondary ingot rose 12 percent from 12,269 tons on hand December 31, 1940, to 13,760 tons on hand December 31, 1941. Shipments in 1941 totaled 297,530 short tons.

Consumption of purchased copper scrap in the United States in 1941, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries: Brass mills		Manufacturers and foundries: Foundries and other manufacturers		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	New scrap	Old scrap	
No. 1 wire and heavy	18,368	42,688	14,126	8,850	2,590	15,542	102,164
No. 2 wire, mixed heavy, and light	10,465	92,175	12,426	1,501	2,689	17,607	136,863
Composition or red brass	35,004	70,480	3		404	59,762	165,653
Railroad-car boxes		1,943				39,159	41,102
Yellow brass	20,348	82,941	232,901	19,875	3,578	18,674	378,317
Auto radiators (unsweated)		45,438				873	46,311
Electrotype shells		1,655				548	2,203
Bronze	307	4,267	2,955		42	1,692	9,263
Nickel silver	765	1,204	6,798	197	96	69	9,129
Low brass	495	727	12,886	1,622		7,087	22,817
Aluminum bronze	133	355			3	1	492
Low-grade scrap and residues	60,773	29,030			45	8	89,856
	146,658	372,903	282,095	32,045	9,447	161,022	1,004,170

The gross weight of "purchased" copper and copper-alloy scrap consumed in 1941 was 1,004,170 short tons compared with 707,924 tons in 1940, a 42-percent increase. Of the total scrap used, 52 percent was consumed by 109 remelters, smelters, and refiners, 31 percent by 36 brass mills, and 17 percent by 1,028 foundries and miscellaneous manufacturers.

Aside from copper-bearing byproduct residues, the remelter, smelter, and refinery group treated comparatively little new scrap but con-

sumed two-thirds of all the old. Brass mills used minor quantities of old yellow brass and old clean copper but accounted for almost two-thirds of all the new scrap reported. Foundries and miscellaneous manufacturers confined virtually all of their purchases to old scrap.

Consumers' stocks of purchased copper-base scrap in the United States at end of year, 1940-41, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1940 [1]	Dec. 31, 1941
Unalloyed copper	15, 606	15, 004
Copper-base alloy	56, 283	53, 218
Low-grade scrap and residues	23, 733	34, 654
	95, 622	102, 876

[1] Revised figures.

Brass-ingot manufacturers placed a voluntary ceiling on their products early in 1941, but sale prices of foundry products were not controlled.

Maximum prices were set for brass mill scrap on July 22, 1941, in order that other consumers might be prevented from offering higher prices to draw new brass and commercial bronze scrap from the channel of most efficient recovery. On August 12, 1941, the price of electrolytic-grade copper was set at 12 cents, delivered Connecticut Valley. This was followed by ceilings on unalloyed copper scrap which placed the consumers' price of No 1 scrap at 10.75 cents, effective August 19, 1941.

Dealers' monthly average buying prices for No. 1 copper scrap at New York rose from 8.87 cents a pound in January to 9.60 cents in March, dropped to 8.99 in April, then rose to 10.03 cents in August. The dealers' buying price ceiling of 10 cents held throughout September, then prices declined to 9.37 cents in November and December. The average was 9.44 cents in 1941 compared with 8.20 cents in 1940. No. 1 composition scrap followed practically the same trends, averaging 9.41 cents a pound in 1941 compared with 7.68 cents in 1940.

The drop in scrap prices during October was occasioned by a revision in the copper price-ceiling order that abolished the dual price schedule and reduced the maximum selling price of No. 1 copper scrap to 10 cents but permitted the addition of transportation charges and certain quantity premiums. The further fall in November prices was the result of an order prohibiting delivery of brass ingot for nondefense uses.

Except for certain grades of brass mill scrap, copper-alloy scrap was free of formal price ceilings until February 27, 1942, when prices were set on 24 grades.

Although primary copper was first made subject to allocation on May 29, 1941, it was not until September 30, 1941, that the flow of copper scrap was brought under regulation. According to Supplementary Order M-9-b issued by the Director of Priorities, brass mill scrap was routed to brass mills as sole consumers, and dealers were prohibited from melting any type of copper or copper-alloy scrap. Deliveries of scrap to other than dealers required a preference rating showing that the material was needed for essential uses.

All types of copper scrap were in demand at the start of 1941, but continued light offerings led to the belief that dealers were holding scrap for an expected rise in price. Liquidation of copper and copper-base scrap was hastened in April, when producers of primary copper agreed to an informal ceiling of 12 cents for refined copper. Brass-ingot makers and custom smelters experienced difficulty in obtaining enough scrap of the better grades throughout 1941, but supplies of material of low copper content exceeded demand. Large purchases of scrap copper and brass were made early in August, when dealers again hurried to move accumulations before formal ceiling prices became effective. Flow of scrap was retarded immediately after the price ceilings were issued and did not increase noticeably until November.

General Imports Order M-63, effective December 27, 1941, required in part that scrap copper and brass be imported under the direction of the Metals Reserve Co Publication of import and export statistics was suspended at the end of September 1941.

Copper, brass, and bronze scrap were placed under export control on January 10, 1941. Effective February 3, 1941, a license was required for exporting materials containing over 15 percent copper.

Brass and copper scrap imported into and exported from the United States, 1940–41, in short tons

	1940	1941 (Jan -Sept.)
Brass scrap imported	1,232	4,688
Scrap copper imported	135	2,023
Brass scrap exported	5,887	681
Scrap copper exported	7,149	3,201

SECONDARY LEAD

The net weight of secondary lead recovered from scrap, including lead as metal and lead contained in alloys, totaled 397,416 short tons valued at $45,305,424 in 1941 compared with 260,346 short tons valued at $26,034,600 in 1940. The value was computed at 5.7 cents a pound in 1941 and 5.0 cents a pound in 1940.

The lead content of soft lead refined from scrap amounted to 75,264 tons, and the lead content of secondary antimonial lead was 206,521 tons in 1941. Lead recovered in other scrap-lead alloys, such as type metal, lead babbitts, and solders, totaled 88,200 tons, and lead recovered as a constituent of other alloy scrap, such as brass and bronze, came to 27,431 tons.

The total secondary lead recovered in all forms represented a 53-percent increase in 1941 compared with 1940.

The apparent drop in the quantity of lead recovered from new scrap—from 33,763 short tons in 1940 to 17,136 tons in 1941—was caused by a change in interpretation and not by any difference in the types of scrap consumed. In former years, certain drosses resulting from the actual use of type metals, as well as drosses produced in scrap-metal dealers' lead-scrap melting operations, were classed as new scrap. Further study has led to the belief that the drosses specified should be reclassified as old scrap. Very little "new" lead scrap

reaches commercial channels, owing to the fact that most of this material is easily prepared for reuse in the same plant.

Secondary lead recovered in the United States, 1940–41, in short tons

	1940	1941
As metal:		
At primary plants	16,588	13,454
At other plants	42,992	61,810
	59,580	75,264
In antimonial lead [1]	126,687	206,522
In other lead alloys	58,586	88,200
In alloys other than lead alloys	15,493	27,430
	260,346	397,416
From new scrap	33,763	17,136
From old scrap	226,583	380,280

[1] Includes 1[illegible],431 tons of lead recovered from secondary sources at primary plants in 1940 and 13,862 tons in 1941.

Production of secondary lead, tin, and lead and tin-alloy products in the United States in 1941, gross weight, in short tons

	Gross weight of product	Secondary metal content

[1] This total includes 7,884 tons of primary metals.
[2] Includes 1,209 tons of antimony from ore.

Refined secondary pig lead totaling 74,959 short tons was produced at 131 plants representing 109 concerns classed as remelters, smelters, and refiners. Of this refined lead, 55,800 tons (74 percent) were produced at only 20 plants.

Production of secondary antimonial pig lead amounted to 226,353 short tons (gross weight), almost all recovered from old storage

batteries. Including lead babbitts, solders, type metals, and miscellaneous lead-base alloys, the total secondary lead and lead-base alloy products reported in 1941 amounted to 409,488 short tons, gross weight. In all, 189 plants were engaged in remelting, smelting, and refining lead and lead alloys, whereas 20 additional smelters and 406 manufacturing plants (mostly foundries) consumed lead and lead-alloy scrap in products other than secondary pig.

It is difficult to draw a distinction between secondary lead smelters and scrap-metal dealers, some of whom melt large quantities of scrap lead in simple pot installations. Measurement of the secondary white metals industry is complicated further by the practice of melting and smelting scrap alloys and drosses containing lead, tin, and antimony to produce so-called "percentage metals," which are pigged and analyzed for subsequent blending in alloys to be sold on specification. For example, solder sweated from lead or copper pipe joints might be thoroughly mixed in a pot, pigged, and analyzed to ascertain the lead and tin contents. The resultant pigs would then be marked and held until an order for solder was received, at which time the alloy would be remelted and the lead-tin proportion adjusted by the addition of either a high-tin alloy or perhaps some very low tin solder stock, until the ratio specified in the order was met. Lead-antimony and lead-tin-antimony scrap alloys are treated similarly, and the percentage metals are used in production of bearing metals, type metals, and antimonial lead.

Although some remelted lead-base and tin-base alloy pigs produced by small remelters are sold directly to manufacturers, others are sold to larger secondary smelters for consumption in specification metals. Thus, percentage metals are reported by the first melter as secondary products recovered from scrap, but the metal contents appear again in the production reports of large smelters. Process metals of this class were deleted from the 1941 statistics to avoid duplication.

Consumption of purchased lead scrap in the United States in 1941, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers [1] and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Soft lead	992	34,591	926	1,212	37,721
Hard lead	539	37,693	117	234	38,583
Cable lead		21,779		70	21,849
Battery-lead plates		257,638		6,552	264,190
Mixed common babbitt	109	6,574		9,077	15,760
Solder	36	9,536		144	9,716
Type metals		15,483	11	3,858	19,352
Dross	7,857	42,345		4,328	54,530
Lead oxide	643	4,650			5,293
Residues	328	6,956			7,284
	10,504	437,245	1,054	25,475	474,278

[1] The lead-base scrap listed as consumed by manufacturers and foundries in 1941 cannot be compared with earlier reports of lead-base scrap consumed by this group in 1940, owing to the recent transfer of 29 large plants (equipped with smelting facilities) from the manufacturer group to the remelter-smelter-refiner group. If the transfer had not been made, this table for 1941 would have shown a total of 343,824 tons consumed by remelters, smelters, and refiners and 130,454 tons of scrap consumed by manufacturers and foundries.

Of the 474,278 short tons of lead-base scrap consumed in 1941, only 11,558 tons (2 percent) were classed as new scrap, and 462,720 tons (98 percent) were old scrap returned for salvage after having served a useful purpose. As usual, battery-lead plates dominated the picture, comprising 56 percent of all lead-base scrap consumed during 1941 and exceeding the 1940 figure by almost 100,000 tons. Reclamation of cable lead dropped slightly, reflecting the tendency of utilities to make existing equipment serve a longer life. A 66-percent increase in consumption of drosses shows that dead stocks of low-grade by-products were brought into the market when a shortage of lead was threatened.

Illinois, with 24 secondary lead remelters and smelters worthy of mention, consumed 19 percent of all lead-base scrap, followed by 17 percent used in Pennsylvania (23 plants), 15 percent in New Jersey (16 plants), 10 percent in Indiana (6 plants), 8 percent in California (14 plants), and 8 percent in New York (27 plants); the remaining 23 percent of consumption was reported by 21 other States.

Consumers' stocks of purchased lead-base scrap in the United States at end of year, 1940–41, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1940 [1]	Dec 31, 1941
Unalloyed lead	4,119	2,733
Lead-base alloy	29,693	25,642
Drosses and residues	8,128	12,775
	41,940	41,150

[1] Revised figures.

Although no formal ceiling prices were applied to scrap lead during 1941, buyers were strongly urged to hold scrap prices to the usual relationship with primary lead quotations. Prices of both primary metal and scrap rose during the first 4 months of 1941 but leveled in April when the trade agreed to an informal ceiling of 5.85 cents a pound for primary pig in New York. Dealers' buying prices for heavy lead scrap in New York averaged 4.72 cents in January, climbed to an average of 5.18 cents in March, then leveled at 5.31 cents in April and stayed there through October. Heavy-scrap-lead prices averaged 5.36 in November and 5.37 in December; the rise was attributed to the expectation of official ceiling prices that would exceed the earlier informal levels. Scrap flow was greatly improved during these 2 months.

Dealers' quotations for battery-lead plates rose steadily from 2.75 cents a pound at the beginning of the year to 3.125 cents in March. The price rose to 3.25 cents in July and increased to 3.50 cents at the end of October in anticipation of a higher price for primary lead.

Battery-plate smelting charges ranged from $16 a ton (maintained through April) to $13 in September, then fluctuated between $13 and $14 until early in December, when the charge fell to $12. On December 18, 1941, quotations jumped to $20 a ton.

Effective January 15, 1942, maximum prices were set for lead-base scrap, battery-lead plates, batteries in boxes, and secondary lead, all in relation to base prices fixed for each of 146 city areas listed as main

shipping points in 34 States. Under the terms of this order, the maximum selling price of heavy-lead scrap in New York was fixed at 5.95 cents a pound, f. o. b. point of shipment. The price of primary pig lead was fixed on the same date at 6.50 cents a pound, delivered at New York.

Secondary lead produced from scrap was made subject to allocation on October 3, 1941. No priority control was exercised on lead scrap throughout 1941, but General Preference Order M-72, issued January 9, 1942, provided for direct allocation of lead scrap when necessary. Acceptance of deliveries of lead scrap at dealers' yards was made dependent on the ratio of shipments to inventories, and monthly reports of dealers' transactions were required.

Lead scrap was placed under export control on March 4, 1941, and effective March 24, 1941, a license was required for exporting materials containing over 15 percent lead.

SECONDARY MAGNESIUM

In 1941, 1,752 short tons of secondary magnesium were recovered. Value was set at $840,960, computed from an average price of 24 cents a pound. This quantity was recovered as 929 tons of magnesium in ingot, 738 tons of magnesium castings, 60 tons of magnesium added as a constituent in aluminum alloys, and 25 tons in reagents.

Secondary magnesium recovered in the United States, in 1941, in short tons

Magnesium alloys produced and recovered from scrap	1, 667
In aluminum alloys	60
In reagents	25
	1, 752
From new scrap	1, 737
From old scrap	15

Production of secondary magnesium [1] and magnesium-alloy products in the United States in 1941, gross weight, in short tons

Magnesium ingot	[2] 929
Magnesium castings	738

[1] This table does not include secondary magnesium recovered in other than magnesium-base products

[2] Approximately 470 short tons of this amount were incorporated in primary magnesium ingot, and the remainder was produced as secondary magnesium ingot

A total of 51 plants consumed 2,279 tons of magnesium-base scrap, which was almost entirely in the form of new scrap emanating from industrial operations. By far the largest tonnage of magnesium scrap consisted of borings and turnings, and this item represented 70 percent of the total; filings and grindings comprised 12 percent, sand castings 10 percent, and miscellaneous items 8 percent. The increased tempo of secondary magnesium consumption was revealed by the fact that 911 tons were consumed in the first 6 months of 1941 compared with 1,368 tons in the latter half of the year. Stocks of magnesium scrap were 204 tons at the start of 1941 and 239 tons at the close.

Sales of magnesium were under strict priority control as of March 24, 1941, and on November 14, 1941, General Preference Order M-2-b, issued by the Office of Production Management, required all

persons owning magnesium of any kind to report its existence by November 30. The new order provided for complete allocation of all magnesium supplies.

Stocks and consumption of magnesium scrap in the United States in 1941, gross weight, in short tons

	On hand—		Consumption during 1941
	Dec. 31, 1940	Dec. 31, 1941	
Cast scrap	20	15	266
Solid wrought scrap	52	22	103
Borings, grindings, drosses, etc	132	202	1,910
	204	239	2,279

To overcome the disadvantages of shipping bulky and inflammable magnesium scrap from scattered sections of the country to the few plants equipped for remelting, additional facilities were provided at strategic locations near the sources of magnesium scrap. On February 25, 1942, four smelting companies with a total of seven plants equipped for handling magnesium scrap were granted the right by the Government to purchase magnesium scrap for remelting into secondary magnesium ingot. Primary magnesium producers continued to remelt scrap from nearby areas.

SECONDARY NICKEL (NONFERROUS)

The 1941 survey of secondary nickel recovery was confined to that recovered from nonferrous scrap, and the incomplete report of nickel recovered in ferro-alloys in former years has been omitted from this report.

Secondary nickel recovered from nonferrous scrap in 1941 totaled 5,315 short tons valued at $3,720,500 compared with 4,152 tons valued at $2,906,400 in 1940. The value for both years was computed at 35 cents a pound, the spot-delivery price of electrolytic nickel, including duty.

Secondary nickel (nonferrous) recovered in the United States, 1940–41, in short tons

	1940	1941
As metal	3	248
In nickel alloys	841	1,267
In copper alloys	3,308	3,396
In chemical products		
Nickel sulfate	(1)	283
Nickel oxide	(1)	120
Nickel chloride, carbonate, cyanide, and nitrate	(1)	1
	4,152	5,315
From new scrap	2,184	3,181
From old scrap	1,968	2,134

1 Data not available.

Owing to the past reluctance of many nickel-scrap consumers to report their activities, figures for 1940 are believed to be incomplete, particularly with respect to nickel recovered as metal.

Production of secondary nickel and nonferrous nickel-alloy products in the United States in 1941, gross weight, in short tons

Refined nickel	79
Nickel anodes	169
Monel-metal bar and shot	289
Cupronickel bar and shot	2, 284
Nickel in chemical products	404

In 1941, 248 short tons of secondary nickel were recovered as metal, which appeared on the market as 79 tons of nickel bars and shot and 169 tons of recast nickel anodes. Production of secondary Monel-metal bar and shot amounted to 289 tons containing 178 tons of nickel, and secondary cupronickel totaled 2,284 short tons containing 1,089 tons of nickel. Of the total secondary nickel reported in nonferrous products, 64 percent was recovered in copper-base alloys represented principally by nickel silver. In addition to nickel as metal and in alloys, 404 tons were recovered in chemical products. Of this amount, 70 percent was in nickel sulfate, and most of the remainder was in nickel oxide, with a total of 1 ton contained in nickel chloride, carbonate, cyanide, and nitrate.

Consumption of purchased nickel scrap in the United States in 1941, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Pure nickel	140	42	105	147	434
Monel metal	383	1, 064	1, 790	74	3, 311
Nickel silver	766	1, 204	6, 894	266	9, 130
Miscellaneous nickel alloys	503	3, 019		2	3, 524
Nickel residues			122	432	554
	1, 792	5, 329	8, 911	921	16, 953

A total of 16,953 tons of nonferrous nickel scrap was consumed in 1941 compared with 12,404 tons in 1940. Nickel silver constituted slightly more than half of the scrap, and Monel metal and miscellaneous nickel alloys were each about one-fifth of the total.

Thirty-six remelters, smelters, and refiners used 42 percent of the total nickel scrap, and 109 manufacturers and foundries consumed the other 58 percent. Of the 9,832 tons of nickel scrap consumed by manufacturers and foundries, 7,025 tons were used by 17 brass mills, and only 2,807 tons were distributed among the remaining 92 plants.

Consumers' stocks of purchased nonferrous nickel scrap in the United States at end of year, 1940–41, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1940 [1]	Dec 31, 1941
Unalloyed nickel	93	60
Nonferrous nickel alloys	2, 217	3, 965
Nickel residues	472	485
	2, 782	4, 510

[1] Revised figures.

Dealers' buying prices for new nickel clips in New York in the first days of 1941 were between 37 and 40 cents a pound, and late in January they rose above 47 cents owing to heavy buying by Japan before export control went into effect. In February, prices dropped to the 30-cent level but gradually rose with increased industrial demand until a 55-cent price was quoted in April. The threat of ceiling prices by the Advisory Commission to the Council of National Defense made quotations nominal until June 2, 1941, when Price Schedule 8 fixed ceiling prices on scrap and secondary material. This action drove the price of clips down to the 24- to 25-cent level. During the latter half of 1941, the dealers' buying price for Monel clips in New York lay between 18 and 19 cents a pound.

Nickel, including scrap, was placed under export control on January 10, 1941, and after February 3, 1941, a license was required for exporting materials containing over 10 percent nickel.

SECONDARY TIN

Recovery of secondary tin rose to 42,033 short tons valued at $43,722,726 in 1941 compared with 33,222 short tons valued at $33,102,401 in 1940. The value was computed at 52.01 cents a pound in 1941 and at 49.82 cents a pound in 1940.

Tin recovered as metal increased to 5,900 tons, a 17-percent rise above the 5,056 tons recovered in 1940. Only seven plants, representing four companies, participated in the recovery of 5,089 short tons of metallic tin from tin-plate scrap in 1941, as the expansion program to accelerate recovery of tin from old cans was not yet under way. The 811 short tons of secondary tin recovered as metal at other plants represented the total reported by 40 remelters, smelters, and refiners and 3 manufacturers. Of this total, 60 tons of remelted tin were reclaimed from scrap tin by dealer-remelters and shipped to smelters for fire refining.

Secondary tin recovered in the United States, 1940–41, in short tons

	1940	1941
As metal		
At detinning plants	4,147	5,089
At other plants	909	811
	5,056	5,900
In copper alloys	13,950	16,298
In lead alloys	7,848	9,509
In tin alloys	5,671	9,188
In chemical compounds	697	1,138
	33,222	42,033
From new scrap	12,736	12,427
From old scrap	20,486	29,606

Almost one-fourth of the 1941 yield of secondary tin was recovered in the form of tin-base products, including metallic tin, tin babbitts, and tin chemicals. The next 40 percent emerged as the tin content of lead-base alloys, and the remaining 36 percent filled the greater part of the tin requirements in secondary brass and bronze products. Metallic tin and tin-base alloy products are listed in the production table in the Secondary Lead section of this chapter.

Block-tin scrap and foil, high-tin babbitts, and tin residues accounted for most of the 43-percent increase in tin-base scrap consumed in 1941. Tin scruff and dross resulting from tin-plate operations in 1941 almost duplicated the 4,936 tons used in 1940.

Dealers' buying prices for block-tin pipe in New York averaged 46.35 cents a pound in 1941 compared with 42.90 cents in 1940. The monthly average rose from 44.50 cents a pound in January to 47.50 cents in May and remained at this price until September, when the average dropped to 45.79 cents a pound. Quotations in each of the last 3 months averaged 45.50 cents.

Consumption of purchased tin scrap in the United States in 1941, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap

Unalloyed tin	214	115
Tin-base alloys	482	624
Drosses and residues	704	1,639
	1,400	2,378

1 Revised figures.

Some small lots of tin scrap were reported sold during the summer months at prices higher than those for primary tin, but warnings from the Office of Price Administration, coupled with the ceiling price of 52 cents a pound for Grade A pig tin, established on August 15, 1941, tended to keep scrap prices fairly well in line.

The price of Grade B tin was fixed at 41.375 cents a pound on September 20, 1941, but no formal ceilings were set on tin-base scrap. There was no Federal control of scrap or secondary tin consumption or stocks before the Japanese attack on December 7, 1941.

Effective December 17, 1941, General Preference Order M-43 provided for allocation of all stocks of pig tin. This order was amended February 14, 1942, to freeze stocks of tin and tin alloys in the hands of manufacturing jewelers, and arrangements were made to purchase all such stocks for the Metals Reserve Co., with the National Lead Co. acting as agent.

On the last day of 1941, Conservation Order M–43–a ordered 50-percent curtailment in the use of tin in nondefense production, with the further provision that use of tin in 29 types of commercial articles should cease March 31, 1942.

General Preference Order M–72 provided for direct allocation of tin-base scrap to consumers when necessary in the interests of the war program. Acceptance of deliveries of tin scrap at dealers' yards was made dependent on the ratio of shipments to inventories in the preceding 60-day period, and monthly reports of dealers' transactions in tin scrap were required to be filed with the Bureau of Mines.

Early in January 1942, retail druggists were urged to set up collection bins for receiving used collapsible tubes of tin or tin-coated lead. Beginning April 7, 1942, consumers were required to turn in a used tube for each new one of toilet preparations purchased. The newly organized Tin Salvage Institute in Newark, N. J., was designated as the agent of the Metals Reserve Co. to reclaim the tin from collapsible tubes.

Detinning plants.—Recovery of tin from new tin-plate clippings was carried out during 1941 at seven plants: Metal & Thermit Corporation operated plants at Carteret, N. J., San Francisco, Calif., and East Chicago, Ind.; Vulcan Detinning Co., at Sewaren, N. J., and Neville Island, Pa.; Standard Metal Refining Co., at Baltimore, Md.; and Johnston & Jennings Co., at Cleveland, Ohio.

New tin-plate scrap treated totaled 341,075 long tons, exceeding the 1940 total of 268,269 long tons by 27 percent. Recovery of tin per ton of scrap treated stayed about the same as during 1940, owing to the fact that general reductions of thickness of the tin coating on steel did not take place until late in 1941.

Recovery of tin from old containers rose only slightly from 62 short tons in 1940 to 69 short tons in 1941.

No tin bichloride or tin crystals have been reported produced from tin-plate scrap since 1939.

Secondary tin recovered at detinning plants in the United States, 1940–41

	1940	1941
Scrap treated:		
Clean tin plate ... long tons	268,269	341,075
Old tin-coated containers ... do	4,963	5,963
	273,232	347,038
Tin recovered as metal:		
New tin-plate clippings ... short tons	4,085	5,020
Old tin-coated containers ... do	62	69
Tin content of tin tetrachloride, tin oxide, and sodium stannate produced ... short tons	697	1,067
	4,844	6,156
Weight of tin tetrachloride, tin oxide, and sodium stannate produced ... short tons	1,157	1,927
Average quantity of tin recovered per long ton of clean tin-plate scrap used ... pounds	35.65	35.69
Average delivered cost of clean tin-plate scrap ... per long ton	$16.59	$18.51

Several small independent plants were equipped for salvaging tin from old cans early in 1942, and six large plants were projected for Government financing. A program was mapped out for converting hot-dipping methods to electroplating of tin to conserve the supply,

and many large city areas arranged early in 1942 to collect empty tin cans for shipment to detinning plants. First reports from the detinning plants revealed that less than half of the old cans received had been properly prepared by washing and flattening.

Export regulations concerning tin-plate scrap adopted in 1940 were continued in force throughout 1941.

Imports for the first 9 months of 1941, mostly from Canada, totaled 15,989 long tons of tin-plate scrap valued at $200,626.

SECONDARY ZINC

The net weight of secondary zinc recovered totaled 283,967 short tons valued at $42,595,050 in 1941 compared with 222,013 short tons valued at $27,973,638 in 1940 (revised). The value was computed at 7.5 cents a pound in 1941 (the average selling price of all grades) and at 6.3 cents in 1940.

Secondary zinc recovered in the United States, 1940–41, in short tons

	1940	1941
As metal:		
By distillation:		
In slab zinc	[1] 48,917	59,306
Zinc dust	17,321	18,950
By remelting	2,704	11,400
	68,942	89,656
In alloys.		
Die-cast slab	([2])	2,571
Copper alloys	[3] 112,306	143,236
In chemical products:		
Zinc oxide	15,810	14,295
Zinc sulfate	1,958	2,840
Zinc chloride	9,132	13,613
Zinc carbonate and cyanide	([2])	348
Lithopone	13,865	17,408
	222,013	283,967
From new scrap	157,809	202,813
From old scrap	64,204	81,154

[1] Gross weight; includes 16,092 tons of zinc slab formerly classified as distilled from plant scrap.
[2] Data not available.
[3] Includes some plant scrap at brass mills.

Twenty-four zinc distillers contributed to a record production of 59,503 tons of secondary distilled slab containing 59,306 tons of zinc. This amount represents a 21-percent increase over the 1940 recovery of 48,917 (revised) short tons. Virtually 40 percent of the supply of secondary distilled slab was consumed by galvanizers, 30 percent by brass mills, 16 percent by die casters, 10 percent by rolling mills and extrusion plants, and the remainder by zinc oxide producers and other miscellaneous users.

The 18,950 tons of secondary zinc dust produced by nine distillers represented approximately 80 percent of the total zinc dust produced in the United States from all sources. More than half of this dust was consumed by the producers of sodium hydrosulfite.

The 2,704-ton figure for remelted zinc listed for 1940 was unusually low, because a large amount of the zinc in scrap used to produce spelter formerly was listed as having been recovered in copper alloys, and spelter produced by dealers was not reported. The 11,400 tons of remelted zinc reported in 1941 was recovered in 10,389 tons of remelt

spelter, 527 tons of galvanizing stock, 497 tons of zinc sheet, 78 tons of zinc powder, and 70 tons of zinc anodes. In addition to the 10,389 tons of remelt spelter listed, 430 tons of remelt spelter were consumed by zinc refiners, and this recovery is included in the weight of redistilled slab produced. Bureau of Mines surveys revealed that 1,967 tons of zinc were recovered in die-cast slab during the first 6 months of 1941, whereas only 604 tons were recovered in the second half.

Zinc is the principal alloying constituent of copper-base alloys, and 143,236 tons of secondary zinc were recovered in secondary brass and bronze. This quantity includes both the zinc originally contained and recovered in brass scrap and the zinc in zinc-base scrap added to secondary brass in the melting furnace.

Production of secondary zinc and zinc alloy products in the United States in 1941, gross weight, in short tons

Redistilled zinc slab	59, 503
Zinc dust	18, 950
Remelt spelter	10, 389
Remelt die-cast slab	2, 735
Galvanizing stock	527
Zinc sheet	497
Zinc powder	78
Zinc anodes	70
Zinc in chemical products	48, 504

Thirty-seven chemical manufacturers recovered 48,504 tons of secondary zinc in chemicals, a 19-percent increase over the 1940 recovery of 40,765 tons. High industrial activity, supplemented by an insufficient supply of titanium pigments, effected a sharp increase in the demand for lithopone at the end of 1941. The production of zinc oxide from zinc scrap and slab zinc declined, but the use of ore for oxide to supply the growing market increased sharply.

A major part of the zinc scrap treated in 1941 consisted of galvanizers' skimmings and dross; and zinc recovery from this source, added to increased recovery of zinc in brass cartridge scrap, explains the recovery of 71 percent of all secondary zinc from new scrap compared with 29 percent from old.

Consumption of purchased zinc scrap in the United States in 1941, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Clippings	3, 978		1, 537		5, 515

	149,637	38,610	32,930	8,336	182,567

[1] Revised figures.

Zinc-base scrap and residues consumed in 1941 totaled 217,093 tons, composed of 39 percent skimmings and ashes, 26 percent dross, 21 percent flue dust and residues, 6 percent die castings, 4 percent sheet, 3 percent clippings, and 1 percent zinc castings.

Of the total zinc scrap used in 1941, Pennsylvania consumed 37 percent, Illinois 17 percent, New Jersey 7 percent, Delaware 6 percent, Oklahoma, West Virginia, Indiana, and Ohio each 5 percent, and all other States 13 percent.

Zinc scrap was used in the following proportion: 76 percent by 130 remelters, smelters, and refiners; 23 percent by 22 chemical plants making chemicals exclusively; and 1 percent by 239 manufacturers and foundries. Of the total secondary zinc recovered in the production of zinc chemicals, 39 percent was reported by concerns that could not be separately classified as chemical works, owing to their greater activity as smelters and refiners. One of the largest reservoirs of zinc was copper-base alloy scrap, from which 30,236 tons of secondary zinc were recovered from new scrap and 47,873 tons from old scrap. For the most part, the scrap containing this zinc was used to make secondary copper alloys such as brass and bronze, but some low-grade brass scrap was put through a copper-recovery process in which most of the zinc content was converted to flue dust.

Of the total zinc scrap consumed, 79 percent represented new scrap. Remelters, smelters, and refiners used 78 percent new scrap and 22 percent old, and chemical works and other manufacturers (and foundries) used 84 percent new scrap and only 16 percent old

Consumers' stocks of purchased zinc-base scrap in the United States at end of year, 1940–41, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1940 [1]	Dec. 31, 1941
Metallic zinc scrap	3,126	1,378
Dross	5,317	5,634
Skimmings and residues	38,503	32,433
	46,946	39,445

[1] Revised figures.

Dealers' buying prices for new zinc clips in New York averaged 6.59 cents a pound in 1941 compared with 4.81 cents in 1940, a 37-percent rise. Prices experienced an inflationary period at the beginning of the year when zinc clips averaged 6.70 cents in January, 7.92 cents in February, and 9.09 cents in March. Pressure on prices encouraged speculation to the point that zinc scrap was withheld from the market, and the prices of zinc scrap materials and secondary slab rose to exceed that of primary slab. As a measure to prevent speculation and to maintain price stability, maximum prices on sales of secondary and scrap zinc were established on March 31, 1941. Secondary slab of Prime Western grade was fixed at 7.25 cents a pound f. o. b. East St. Louis, and High-Grade zinc was set at 8.25 cents.

The maximum dealers' selling price for new zinc clips was set at 6.75 cents delivered at buyers' plants. This ceiling forced the average dealers' buying prices down to 5.87 cents in April, where it remained through September. In October, the Office of Price Administration raised the price of Prime Western secondary zinc to 8.25 cents, and the selling price of zinc clips was adjusted to 7.25 cents. This accounted for the 6.87-cent average dealers' buying price maintained through November and December. A formal ceiling order on January 29, 1942, forced adherence to primary zinc prices previously held down by informal agreement.

Throughout 1941 the zinc industry was under close surveillance of the Government. On April 1, a monthly production pool was established from which the Office of Production Management allocated zinc to meet emergency demands. The amount reserved for this pool each month increased from 3,000 tons in April to over 24,000 tons in November.

On July 1, 1941, the zinc industry was put under full priority control by General Preference Order M-11. This order continued the zinc pool so as to include production of all grades of distilled zinc, both primary and secondary, as well as zinc oxide and dust. The zinc that remained after the required amount had been set aside in the pool was to be shipped in such manner that each customer should receive a percentage of the producers' commitments to him for the month, including both defense and nondefense orders, equal to the percentage received by every other customer. These restrictions also applied to interplant transfers and toll agreements and included galvanizers who redistilled zinc from dross or skimmings.

Imports of metallic zinc scrap into the United States for the first 9 months of 1941 totaled 59 tons compared with 164 tons for the whole year 1940, and imports of zinc dross and skimmings were 353 tons for 9 months of 1941 compared with 356 tons in 1940. There were 519 tons of skimmings imported through September 1941 for smelting, refining, and reexporting. Zinc scrap was placed under export control on January 10, 1941, and effective February 3, 1941, a license was required for exporting materials containing over 15 percent zinc.

IRON AND STEEL SCRAP [1]

By Harold E. Carmony

SUMMARY OUTLINE

GENERAL SUMMARY

Under the impetus of greatly increased activity in war industries, steel-ingot production in 1941 surged to unprecedented heights, creating the greatest demand for iron and steel scrap ever known. The production of steel ingots in 1941 increased 24 percent over that in 1940. Reflecting this rise in steel-ingot production, the use of ferrous scrap increased 33 percent over that consumed in the previous record year—1940. This greater increase in the use of scrap as compared with the rise in the steel-ingot production was necessitated by the relatively smaller increase in pig-iron production, which rose 20 percent over 1940. During the first 6 months of 1941, scrap consumption was fairly stable, but with the accelerated rate of war-material manufacture, demand improved as steel production soared to record proportions in the closing months of the year. The consumption of scrap probably reached an all-time peak in October 1941. Despite the large increase in demand, prices increased only slightly as a result of price-control activities of the Federal war agencies. Stocks of iron and steel scrap consistently declined throughout the year. During November and December, many consumers were obliged to increase the amount of pig iron used because of the curtailment of available supplies of scrap caused by the continued large demand.

The total consumption of ferrous scrap and pig iron in 1941 increased 27 percent over that in 1940. Of the 115,401,728 net tons used, 93,042,313 tons were charged to steel-making furnaces and 22,359,415 tons to iron furnaces. In making the average ton of steel in 1941 more scrap and less pig iron were used than in 1940; the relative consumption of home scrap increased considerably in 1941 over 1940, and that of purchased scrap increased slightly. In iron furnaces the relative use of total scrap also increased, and that of pig iron decreased. This increase in the relative use of scrap resulted from larger consumption of home scrap in 1941 compared with 1940. The proportion of purchased scrap used increased only slightly.

Statistics on exports of ferrous scrap from the United States in 1941 are not available for publication, except the total amount exported during the first 9 months of the year. However, from the data pro-

[1] Minerals Yearbook, 1939, p. 513, defines the various scrap terms used in this report.

curable, it is evident that exports were considerably lower in 1941 than in 1940 and previous years. The exportation of scrap was limited, by restrictions imposed by the Federal Government in October 1940, to countries of the Western Hemisphere and the United Kingdom. Two joint resolutions that would directly or indirectly impose restrictions on the exportation of scrap from all the Territories, dependencies, and possessions of the United States were introduced during the first session of the Seventy-seventh Congress. After extensive testimony, one of these, S. J. Res. 76, was approved on May 28, 1941, and became Public, No. 75, 77th Congress. Also introduced was a bill designed to suspend the effectiveness, during the national emergency, of tariff duties on scrap iron, scrap steel, and nonferrous-metal scrap, but the Congress adjourned without acting on the proposed legislation.

Since the outbreak of war in 1939 there has been no cartel activity by foreign consumers for the purpose of securing scrap for exportation from the United States. Consequently, all countries that purchased scrap in 1941 acted independently.

Prices for scrap fluctuated within narrower limits in 1941 than in 1940. This smaller fluctuation did not result from actual supply-demand relationships, but from the attempts of the scrap industry to conform to the request of the Government to voluntarily halt the advancing trend in scrap-steel prices. During the first quarter of 1941, the price stabilization agency of the Government continued the conferences, initiated in the latter months of 1940 between steel-mill and scrap-trade representatives, designed to achieve voluntary reduction in scrap prices. However, the effect of these conferences was only partly successful. According to Iron Age, the quotation for No. 1 Heavy-melting steel scrap at Pittsburgh declined from a high of $23.75 a gross ton the first week in January 1941 to a low of $20.75 the second week in February but then increased slightly to $21.00. On April 3, 1941, the Government issued Price Schedule 4, establishing maximum prices for iron and steel scrap. Under this schedule, the price of No. 1 Heavy-melting steel scrap was stabilized at $20.00 at Pittsburgh with other grades and districts based thereon. The resultant average price for 1941 was $20.34 compared with $19.26 in 1940 and was the highest since 1923, when the average was only a few cents higher. Scrap prices received strong support from both the domestic and foreign markets—support created by increased domestic demand and the need for scrap by the democratic nations. The price of basic pig iron, established at $23.50 per gross ton at Valley furnaces in December 1940, prevailed throughout 1941.

The continued high operating rates in steel production during the earlier part of the year precipitated such an abnormal demand for scrap that dealers and brokers found it difficult to cover commitments. This occasioned considerable alarm as to the depleted condition of domestic stocks of iron and steel scrap. Consequently, the Priorities Division, Office of Production Management, issued General Metals Order 1. Designed to conserve existing supplies, this order restricted accumulation of inventories and eliminated excessive inventories by curtailing deliveries. The quarterly surveys inaugurated by the Bureau of Mines in September 1939 to ascertain the stock situation were continued through the first 6 months of 1941, at which time they were expanded and conducted upon a monthly basis. Since the scrap-supply situation, as shown by these surveys, did not improve satisfactorily the Priorities Division in October issued General Preference

Order M–24, devised to conserve the supply and direct the distribution of iron and steel scrap, and placed scrap under full priority control, allocating it in a manner similar to pig iron. At the same time the Bureau of Mines expanded its monthly iron and steel scrap surveys, furnishing the results to the Office of Production Management and other defense agencies for their confidential use. The survey of suppliers', producers', and consumers' stocks at the end of 1941[2] indicated inventories approximating 4,994,000 net tons, which was equivalent to a 4-week supply at the December rate of consumption. This showed a declining trend in iron and steel scrap stocks, as surveys conducted earlier in the year indicated that inventories were equivalent to a 5- to 6-week supply at the rate of consumption at that time. Consumers' stocks of scrap decreased from 5,471,554 tons at the beginning of 1941 to 3,726,030 tons at the close.

Salient statistics of ferrous scrap and pig iron in the United States, 1940–41

	1940	1941	Change in 1941 (percent)
Stocks, December 31:			
Ferrous scrap and pig iron at consumers' plants:	*Net tons*	*Net tons*	
Home scrap	1,783,920	1,166,551	−35
Purchased scrap	3,687,634	2,559,479	−31

497779—43——35

Figure 1 shows the consumption of purchased scrap and the output of pig iron and steel ingots and castings from 1905 to 1941, inclusive.

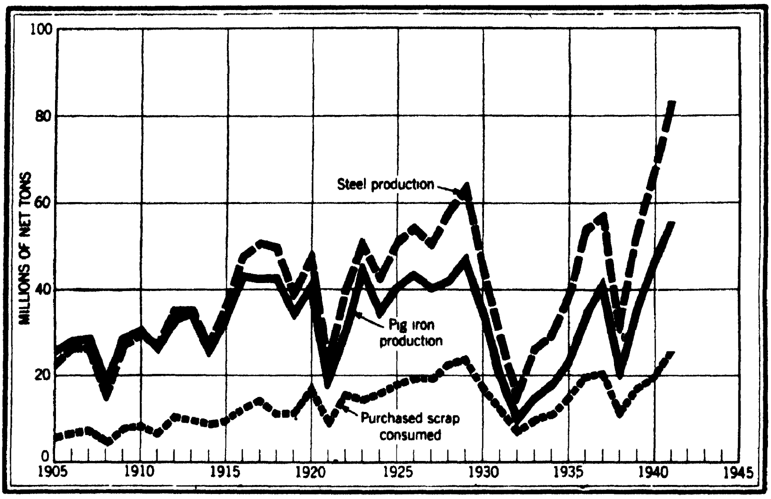

FIGURE 1.—Consumption of purchased scrap and output of pig iron and steel in the United States, 1905–41. Figures on consumption of purchased scrap for 1905–32 are from *State of Minnesota* vs. *Oliver Iron Mining Co. et al.*, Exhibits, vol. 5, 1935, p. 328; those for 1933–34 are estimates by authors; and those for 1935–41 are based upon Bureau of Mines reports Figures on output of pig iron and steel are as given by the American Iron and Steel Institute.

PRICES[3]

Scrap prices in 1941 were moderate, especially in view of the fact that steel-ingot production with the exception of 2 weeks consistently exceeded 95 percent of rated capacity. Market quotations for No. 1 Heavy-melting steel and No. 1 Cast cupola scrap, which had averaged $22.80 and $22.65 a gross ton (Pittsburgh), respectively, in December 1940, eased off; No. 1 Heavy-melting steel dropped to $20.75 in the second week of February, and No. 1 Cast cupola scrap dropped to $21.75 in the second week of January. This moderate price schedule was due not to market conditions but rather to pressure applied by the Price Stabilization Division of the Advisory Commission to the Council of National Defense for voluntary cooperation by the scrap industry to stabilize scrap prices. However, competition for supplies was too keen to permit a voluntary stabilization program to operate successfully, and prices soon resumed an upward trend. No. 1 Heavy-melting steel reached $21.00 the third week in February and No. 1 Cast cupola scrap rose to $23.25 the third week in March. Prices remained at these levels until the first week in April, when the Price Stabilization Division, later known as the Office of Price Administration, issued Price Schedule 4 establishing maximum prices for iron and steel scrap. Under this schedule No. 1 Heavy-melting steel, at Pittsburgh, was set at $20.00 per gross ton and was maintained throughout the remainder of the year at this point. The established prices for other grades of steel scrap were based upon the price of No. 1 Heavy-melting steel, and price differentials for other districts were standardized, using the Pittsburgh prices as a basis. The price for No. 1 Cupola cast was established at no more than $2.00

[3] Pittsburgh price quotations from Iron Age.

per gross ton under the price of No. 2 Foundry pig iron, delivered at the same point. On May 7, 1941, the price of No. 1 Cupola cast was changed to $22.00, Pittsburgh, with differentials for other districts based upon this price.

There were several minor revisions of Price Schedule 4 throughout the year, which included changes in export prices, addition or deletion of basing points, modification of shipping-point prices, and an increase in prices for scrap in remote States. On December 23, 1941, a major revision in the price structure was introduced with a view toward increasing the collection of all kinds of scrap and directing the flow of particular types to plants of consumers needing special scrap items. This revision classified the various types and grades of scrap according to use and established maximum prices for each type of consumer; however, the basic price remained unchanged. In this new amendment the price of No. 1 Cupola cast was changed from the basing-point system to an f. o. b. shipping-point price under which the United States was divided into three groups containing certain specified States, the price varying according to the location of the group.

In contrast to the fluctuations in scrap prices, the price of basic pig iron, established at $23.50 a gross ton at Valley furnaces late in December 1940, remained unchanged throughout 1941.

On May 29, 1941, the Office of Price Administration and Civilian Supply, acting under an Executive order, issued Price Schedule 8 governing scrap and secondary materials containing nickel. This schedule included stainless steel and nickel-steel scrap.

Export scrap prices for the first 9 months of 1941, as indicated by the declared value of iron and steel-scrap exports, averaged $18.56 a gross ton and were much higher than the 1940 average of $16.87. The 1941 average price—$18.56—was slightly less than the recent highest yearly average—$18.91—which was attained in 1937. The price structure during the first 4 months of 1941 was relatively strong due to the difficulty of obtaining material for loading, but after this period the prices were fairly well established under Price Schedule 4. The average value of exports in April—$19.62—represented the high monthly average for the 9 months for which statistics are available. After April export values declined, reaching the low point of the first three quarters of the year in September when the average was $17.38 a ton.

LEGISLATION

Since H. R. 9850, Seventy-sixth Congress, authorizing licensing of exports was approved and became Public, No. 703, no new bills advocating further restrictions on the exportation of iron and steel scrap have been introduced. However, two joint resolutions extending the application of Section 6 of Public, No. 703, Seventy-sixth Congress, to all Territories, dependencies, and possessions of the United States were introduced during the first session of the Seventy-seventh Congress. After much debate in both the Senate and the House of Representatives, Representative May's resolution (H. J. Res. 183, 77th Cong.) was tabled, and Senator Reynolds' resolution (S. J. Res. 76, 77th Cong.) was approved and became Public, No. 75, on May 28, 1941. Section 6 of Public, No. 703, Seventy-sixth Congress, and Public, No. 75, Seventy-seventh Congress, provide for the licensing, under proclamation by the President, of exports of materials deemed

necessary in the interest of national defense. Acting under these laws, the President on May 28, 1941, proclaimed that all articles and materials described in previous proclamations issued pursuant to section 6 shall not be exported from the Territories, dependencies, and possessions of the United States, including the Philippine Islands, the Canal Zone, and the District of Columbia, except when authorized in each case by license. One bill[4] calling for the suspension of tariff duties on scrap metal was introduced during this session, but Congress adjourned without acting on the bill, deferring further consideration to the 1942 session of the Seventy-seventh Congress.

On May 1, 1941, the Priorities Division, Office of Production Management, acting under an Executive order signed by the President, issued General Metals Order 1 to restrict inventory accumulations of certain specified materials. This order, designed to conserve existing supplies of certain specified materials, including iron and steel scrap, restricted inventory accumulation and eliminated excessive inventories by curtailing deliveries. Then, on October 11, 1941, the Priorities Division issued General Preference Order M-24 to conserve the supply and direct the distribution of iron and steel scrap. Under this preference order, iron and steel scrap was placed under full priority control, and allocation of scrap was inaugurated in a manner similar to the allocation of pig iron.

STOCKS

Visible supplies of iron and steel scrap and pig iron in the United States were determined by the regular annual canvass of consumers of these materials and the monthly canvass of suppliers and producers. The monthly canvass had been expanded to include as suppliers all dealers and automobile wreckers and as producers all railroads and manufacturing plants that produced 50 tons of scrap in a month. The final results of the annual survey indicate that consumers', suppliers', and producers' stocks of iron and steel scrap totaled 4,917,399 net tons on December 31, 1941. This total of 4,917,399 tons represents a 36-percent decrease from the 7,662,865 tons on hand December 31, 1940, even with the addition of a large number of concerns that were not canvassed in the previous year.

Consumers' stocks.—Consumers' stocks of home and purchased scrap were considerably less at the end of 1941 than at the beginning of the year. The supply of 1,166,551 net tons of home scrap on hand December 31, 1941, represented a 35-percent decrease from the 1,783,920 tons on hand at the beginning of the year, and the supply of 2,559,479 tons of purchased scrap on hand at the end of 1941 was a 31-percent decrease from the 3,687,634 tons on hand December 31, 1940. Thus, consumers' stocks of scrap totaling 3,726,030 tons at the year end were 32 percent less than the 5,471,554 tons on hand at the beginning of the year.

Likewise, consumers' stocks of pig iron totaling 1,585,199 tons at the end of the year had decreased 51 percent from the 3,242,324 tons on hand at the beginning of the year.

Suppliers' and producers' stocks.—In appraising stocks insofar as suppliers and producers are concerned, it should be noted that the coverage of the canvass is not known precisely. However, the data

[4] H. R. 5985. To suspend the effectiveness, during the existing national emergency, of tariff duties on scrap iron, scrap steel, and nonferrous-metal scrap.

Consumers' stocks of ferrous scrap and pig iron on hand in the United States on December 31, 1940, and December 31, 1941, by States and districts, in net tons

assembled include virtually complete returns from the larger suppliers and producers, as well as a representative number of returns from others, and the figures shown probably reveal a very substantial part of the total visible supplies of iron and steel scrap in suppliers' and producers' hands.

Stocks held by dealers, automobile wreckers, railroads, and manufacturers declined from 2,191,311 net tons on December 31, 1940, to 1,191,369 tons on December 31, 1941, or 46 percent. Stocks in the hands of the larger suppliers were 76 percent lower at the end of 1941 than at the end of 1940, and railroad inventories declined 43 percent during the same period.

CONSUMPTION

In the canvass of consumers of ferrous scrap and pig iron, data are assembled only on that portion of scrap used in remelting processes. To simplify the annual canvass, no details are sought regarding the ordinary trade classifications of scrap consumed, and no attempt is made to obtain data on its value or cost at consumers' plants. Statistics are compiled to show the consumption of scrap and pig iron by districts and States and by types of furnace. To avoid disclosing details concerning individual plants reporting it is necessary in some instances to combine figures for some States. All such combinations are made with a view to revealing details of consumption by types of furnace rather than by geographic subdivisions.

The importance of scrap in the conservation of resources is illustrated by the relative quantities of scrap and ore used in the domestic iron and steel industry. The total scrap consumed in 1941 was equivalent to 123 percent of the iron content of all domestic and foreign iron and manganiferous ores used in blast furnaces, and purchased scrap alone equaled 53 percent of the iron content of the ores; in 1940 the comparable percentages were 111 and 48.

Scrap constitutes by far the greater part of the ferrous raw materials used in iron and steel plants in the Southwestern, Pacific Coast, and New England districts. These regions, however, used less than 5 percent of the total scrap consumed in 1941. In the New England district proportionately less scrap was used in 1941 than in 1940; whereas in the remaining districts (Middle Atlantic, Southeastern, Southwestern, North Central, Rocky Mountain, and Pacific Coast) proportionately more scrap was used.

Open-hearth steel furnaces use by far the largest quantities of ferrous scrap and pig iron. They consumed 67 percent of the total scrap in 1941 (70 percent in 1940), 71 percent of the home scrap (73 percent in 1940), 63 percent of the purchased scrap (65 percent in 1940), and 75 percent of the pig iron (79 percent in 1940).

In cupola furnaces, the second-largest consumers of scrap, the relative consumption of home and purchased scrap did not change from 1940, when the percentages were 15 and 22, respectively; however, their consumption of pig iron increased to 10 percent in 1941 from 9 percent in 1940.

Ferrous scrap and pig iron consumed in the United States and percent of total derived from home scrap, purchased scrap, and pig iron, 1940–41, by districts

[1] Includes data for 3 Brackelsberg furnaces.

Open-hearth and cupola furnaces together consumed 86 percent of the home scrap and 85 percent of both purchased scrap and pig iron in 1941. Bessemer converters used 11 percent of the pig iron consumed in 1941 but only relatively small quantities of scrap (0.66 percent of the total). Although electric furnaces consumed only 7 percent of the total scrap in 1941, 98 percent of the total charge to this type of equipment was home and purchased scrap.

[1] Includes some pig iron used in making direct castings.
[2] Where 2 or more separate departments, such as blast-furnace, open-hearth, foundry, etc., are situated at the same place and are operated by 1 establishment, each appears as 1 plant in the total.

CONSUMPTION BY DISTRICTS AND STATES

All 48 States, the District of Columbia, and Alaska contain plants consuming ferrous scrap or pig iron. The greatest consumption, however, is concentrated in the steel-making centers of the North Central, Middle Atlantic, and Southeastern States. These areas include the 8 largest consuming States, which used 83 percent of the total scrap, 92 percent of the pig iron, and 87 percent of the total scrap and pig iron charged into furnaces in 1941; these percentages remained unchanged from 1940. These States (the relative position of which did not change from 1940) and the percentage of the total ferrous scrap and pig iron each consumed in 1941 were as follows: Pennsylvania 28, Ohio 20, Indiana 11, Illinois 9, Michigan 5, New York 5, Alabama 5, and Maryland 4.

The following table shows the total consumption of ferrous scrap and pig iron by districts and the percentage change in the use of home scrap, purchased scrap, total scrap, and pig iron from 1937 to 1941.

Consumption of ferrous scrap and pig iron in the United States, 1937–41, by districts

District and year	Active plants reporting	Scrap: Home, Net tons	Scrap: Home, Change from previous year (percent)	Scrap: Purchased, Net tons	Scrap: Purchased, Change from previous year (percent)	Scrap: Total, Net tons	Scrap: Total, Change from previous year (percent)	Pig iron, Net tons	Pig iron, Change from previous year (percent)

CONSUMPTION BY TYPE OF FURNACE

Open-hearth furnaces.—Ferrous scrap and pig iron consumed in open hearths in 1941 totaled 82,404,890 net tons—a 22-percent increase over 1940. Of the 1941 total, home scrap constituted 29 percent, purchased scrap 19 percent, and pig iron 52 percent; in 1940 the percentages were 27, 19, and 54, respectively. The use of home scrap increased 31 percent, purchased scrap 25 percent, and pig iron 17 percent.

Charges to open-hearth furnaces in 1941 consisted of 48 percent total scrap and 52 percent pig iron compared with percentages in 1940 of 46 and 54, respectively. Of the total scrap consumed in open hearths in 1941, 40 percent was purchased scrap compared with 41 percent in 1940 and 44 percent in 1939. Higher proportions of purchased scrap are used in areas remote from pig iron-producing centers, but the practice of using scrap exclusively is relatively rare. In 1941 only 4 plants out of a total of 139 operated upon a 100-percent scrap basis; they consumed only 501,842 tons, less than 1 percent of the total consumption of ferrous raw matrials in open hearths.

Pennsylvania, the leading steel-producing State, outranked all others in 1941 in the consumption of ferrous scrap and pig iron in open hearths, followed by Ohio, Indiana, and Illinois.

Bessemer converters.—The consumption of ferrous scrap and pig iron in bessemer converters in 1941 totaled 6,386,508 net tons—a 56-percent increase over 1940. This large increase in total consumption indicates a revival of the use of bessemer converters for steel making. The proportion of scrap consumed in converter practice is low (amounting to only 6.2 percent in 1941), and the major portion was home or plant scrap. Almost all of the small tonnage of purchased scrap consumed in converters was used in small steel-foundry plants.

Pennsylvania was the principal consumer of scrap in bessemer converters in 1941.

Consumption of ferrous scrap and pig iron in bessemer converters in the United States in 1941, by districts and States, in net tons

Electric steel furnaces.—Ferrous scrap and pig iron consumed in electric furnaces in 1941 totaled 4,250,915 net tons—a 67-percent increase over 1940. Pig iron constituted less than 2 percent of the total ferrous raw materials used in electric furnaces in 1941. Of the 306 active plants reporting in 1941, 104 operated exclusively on scrap and consumed 751,711 tons—about 18 percent of the total scrap and pig iron used.

Ohio led all States in 1941 in the consumption of scrap in electric furnaces, followed by Pennsylvania, Michigan, Illinois, and New York.

Consumption of ferrous scrap and pig iron in electric steel furnaces in the United States in 1941, by districts and States, in net tons

Cupola furnaces.—Consumption of ferrous scrap and pig iron in cupola furnaces in 1941 totaled 15,952,884 net tons—a 31-percent increase over 1940. Use of home scrap increased 37 percent, purchased scrap 27 percent, total scrap 32 percent, and pig iron 31 percent. Thus, the proportionate increase in the use of purchased scrap was less than that of pig iron, although the prices of scrap were relatively lower as compared with pig iron. This lower proportion of purchased scrap was undoubtedly caused by difficulty in obtaining cast scrap.

Charges to cupola furnaces in 1941 consisted of 31 percent home scrap, 35 percent purchased scrap, and 34 percent pig iron; in 1940 the percentages were 30, 36, and 34, respectively. Many cupola plants operate on a 100-percent scrap charge; a total of 511 plants reported the use of 922,685 tons of ferrous scrap without pig iron in 1941 compared with 456 plants that reported the use of 1,086,456 tons in 1940.

The relative position of States that are large consumers of scrap in cupola furnaces was not changed in 1941. Michigan continued to be the principal consumer, followed in order by Ohio, Pennsylvania, Illinois, and New York.

Consumption of ferrous scrap and pig iron in cupola furnaces in the United States in 1941, by districts and States, in net tons

[1] Includes some pig iron used in making direct castings.

Air furnaces.—Ferrous scrap and pig iron consumed in air furnaces in 1941 amounted to 1,826,487 net tons—a 79-percent increase over 1940. The use of home scrap increased 108 percent, of purchased scrap 54 percent, and of pig iron 62 percent; the use of total scrap increased 89 percent. Thus, equipment of this type used relatively more pig iron than purchased scrap in 1941, in contrast with 1940 when the relative increase in use of both was identical. No air-furnace operators reported exclusive use of scrap in 1941, whereas in 1940 4 reported the use of 15,673 tons.

Ohio led all States in 1941 in the consumption of scrap in air furnaces, followed in order by Illinois, Pennsylvania, Indiana, Michigan, New York, and Wisconsin.

Blast furnaces.—Ferrous scrap constitutes only a small proportion of the metal-bearing materials consumed in blast furnaces. The other materials used in 1941 were 94,404,667 net tons of iron and manganiferous iron ores, 6,858,576 tons of cinder and scale, and 3,983,000 tons of flue dust. Total consumption of scrap in 1941, as reported by 78 plants operating blast furnaces, was 2,904,938 tons, a 40-percent increase over 1940. Of the 1941 total, 55 percent was home scrap and 45 percent purchased scrap.

The proportion of scrap used in blast furnaces increased in 1941, amounting to 5.3 percent of the pig iron produced in 1941 compared with 4.5 percent in 1940 and 5.6 percent in 1939. Purchased scrap was equivalent to 2.4 percent of the pig iron produced in 1941 compared with 1.7 percent in 1940 and 2.3 percent in 1939.

Blast furnaces in Ohio continued to consume more scrap than those in any other State and in 1941 used 8 percent more than Pennsylvania, the second ranking State; in 1940, Ohio furnaces consumed 3 percent more than Pennsylvania furnaces.

[1] Electric furnace.

FOREIGN TRADE [5]

Statistics on foreign trade during 1941 are not available for publication, except totals covering the period from January through September. Therefore no accurate conclusions or comparisons with previous years can be made.

Imports.—Imports of iron and steel scrap into the United States, which never have been very significant, totaled 52,429 net tons valued at $503,100 during the period from January through September 1941. In 1940, 2,199 tons valued at $47,979 were imported. Of the 1941 partial total, 27,822 tons came from Cuba, 17,601 from Canada, 2,317 from Colombia, 1,859 from Curaçao (N. W. I.), 1,117 from Surinam, 756 from Europe (mainly Czechoslovakia), 736 from Bermuda, and only 221 from other countries. In addition, 17,908 tons of tin-plate scrap were imported during the first 9 months of 1941, largely from Canada. In 1940 imports of tin-plate scrap totaled 18,609 tons compared with 14,149 in 1939.

Exports.—Ferrous scrap exports (all types) from the United States during the January–September period of 1941 totaled only 696,110 net tons valued at $12,050,641. In 1940, 3,159,284 tons valued at $48,314,146 were exported. The low exportation in 1941 was caused

[5] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

by license proclamations issued during the latter part of 1940 restricting exports of all grades of scrap, except to Great Britain and countries of the Western Hemisphere. The shipments in 1941 included 9,989 tons of tin-plate scrap, waste-waste tin plate, tin-plate strips, cobbles, etc., valued at $654,946. In 1940, exports of this type of scrap totaled 15,923 tons valued at $753,184. The following table shows the principal countries to which shipments of scrap were consigned during the 5-year period 1936–40.

Ferrous scrap exported from the United States, 1936–40, by countries, in net tons

Country	1936	1937	1938	1939	1940
Canada	71,357	207,840	103,283	196,556	411,571
Germany	7,615	98,731	258,611	18,574	
Italy	319,341	427,161	486,883	477,004	357,627
Japan	1,184,536	2,140,889	1,547,617	2,279,315	1,079,141
Netherlands	5,350	160,609	231,341	60,665	165
Poland and Danzig	34,837	308,680	109,625	173,161	
United Kingdom	408,659	948,838	433,829	569,288	1,100,774
Other countries	136,773	300,987	127,233	240,009	210,006
	2,168,468	4,593,735	3,358,422	4,014,572	3,159,284
Total value	$24,684,084	$79,387,459	$45,829,533	$55,911,516	$48,314,146

Exports were drawn largely from seaboard areas where the cost of transportation from the point of origin to the port of exportation is relatively low and where the cost of transportation to domestic iron and steel plants not within the area is high.

WORLD ASPECTS

Statistics on world steel and pig-iron production in 1941 are not available, as publication of information has been suspended in many countries. However, as iron and steel are essential to the military forces, world steel and pig-iron production undoubtedly was considerably increased, and the demand for iron and steel scrap was greater than at any previous time.

CARTEL ACTIVITIES

All agencies that formerly operated on behalf of groups of countries suspended operations after the advent of war in 1939, hence there was no activity for the purchase of iron and steel scrap by any cartel for individual nations. Throughout 1941 each nation that purchased scrap bought independently; the pro-Axis nations procured no scrap, and the democracies received less scrap than in 1940.

REVIEW BY COUNTRIES

Canada.—Steel production in Canada reached new high levels in 1941, when the output of steel ingots and castings totaled 2,701,000 net tons, an increase of approximately 20 percent over the previous record of 2,256,000 tons established in 1940. Canadian pig-iron production also increased in 1941 but not to the extent of the increase in steel production, indicating that the steel industry was more dependent on supplies of iron and steel scrap to establish the new record. Production of pig iron in 1941 totaled 1,528,000 tons compared with the previous record of 1,309,000 tons established in 1940, an increase of

less than 17 percent.[6] This increased production of steel and pig iron occasioned alarm regarding the scrap supply since, with the greater demand that at times exceeded the supply, dealers could not increase their yard stocks, and some consumers were compelled to deplete stock piles to maintain production.[7]

On February 17 1941, iron and steel scrap was placed under the direct control of the Canadian Steel Controller, and maximum prices for steel scrap only were issued. This measure was instituted to relieve the price situation and to insure the maximum flow of scrap through domestic channels.[8] Then, on July 10, 1941, the Steel Controller also established a maximum price schedule for cast-iron scrap to assure a steady flow of this material to foundries and to stabilize prices.[9] During the last quarter of the year the entire iron and steel scrap industry was placed under Government control, under which all dealers were required to procure a license from the Steel Controller, comply with maximum prices, and submit monthly reports.[10] The program instituted in 1940 by the Dominion Government, to collect agricultural scrap, as well as old ship hulls, automobile scrap, and railroad material in the maritime Provinces and rural districts, was continued and enlarged to include industrial concerns, municipal governments, and the civilian population.[11] To utilize supplies of scrap metal that accumulated in British Columbia, as a consequence of the embargo on exports and the difficulty of transporting scrap to consuming centers, the Government endorsed the establishment of a steel plant in which scrap would be utilized exclusively.[12] No iron and steel scrap has been exported from Canada since late in 1939, except to the United Kingdom and to nations of the Western Hemisphere. Consequently, exports have decreased considerably, whereas imports from the United States have steadily increased.

Germany.—Statistics on the production of steel and pig iron and on the consumption of scrap in Germany are not available. However, as a result of annexation and military occupancy of European countries, steel-ingot capacity is estimated as more than double what it was before the war.[13] The German Government issued a decree curtailing the use of iron and steel in many commodities, except in goods to be used for military or hospital purposes.[14] Decrees were also issued in German-dominated countries regulating the use and disposal of scrap materials. Iron and steel scrap was shipped from such countries for use in the manufacture of war materials.[15]

Japan.—The prohibition by the United States of exports of iron and steel scrap to Japan caused a revision of technique in the iron and steel industry.[16] The main point in the revised plans included the increased manufacture of equipment for the production of steel from pig iron, thereby using little or no scrap. Some small success was attained in furnaces of low capacity in producing steel using approximately 15 percent scrap and 85 percent pig iron, as compared with previous practice when these percentages were 45 and 55, re-

spectively. In view of the scarcity of scrap the Ministry of Commerce decided to request steel-manufacturing companies to use a ratio of 70 percent pig iron to 30 percent scrap in the production of steel.[17] To offset the loss of scrap imports, the Government intensified scrap-collection efforts, and such material as railway cars, posts, kitchen utensils, gutters, pipes, and manhole covers was salvaged. Fences around Government and business buildings were salvaged, as were the numerous ships that have been wrecked in nearby Japanese-controlled areas.[18] The iron and steel industrial policy as regards the purchase and distribution of scrap iron, which had been inaugurated previously, was extended to provide for closer control of the allotment of iron and steel raw materials.

United Kingdom.—Scrap remained an extremely significant factor in the production of steel in the United Kingdom in 1941, especially since operations at iron and steel mills were conducted at or near record levels throughout the year. Imports of scrap from the United States continued until September, when a decision was reached to discontinue the exportation of scrap materials from the United States to Great Britain.[19] House-to-house collection campaigns were continued and produced sizable quantities of scrap. In addition to these collections, scrap was being salvaged from buildings damaged by the enemy, derelict factories, abandoned railroad and street-car installations, and other sources of supply. Buildings damaged by bombs yielded large quantities of iron and steel scrap, offsetting the curtailment of imports. Local authorities were instructed to compile a list of all unnecessary gates and railings, with the exception of those serving a safety purpose or having historic interest or artistic merit.[20] These measures tended to increase the supply of scrap material, with the result that at the end of the first half of the year stocks of iron and steel scrap were approximately 50 percent larger than during 1940, and adequate supplies were available throughout the entire year 1941.[21]

The British Ministry of Supply issued Control of Iron and Steel (Scrap) Order 14, which decreed complete control over all buying and selling of scrap.[22] This decree regulated the acquisition or disposition of scrap except by license; exports of scrap were also prohibited except under license issued by the Export Licensing Department of the Board of Trade. In conjunction with this decree, maximum prices were established covering all sales of iron and steel scrap. Toward the close of the year the scrap-collection drives were placed upon a firmer national basis and were being directed by the Ministry of Works and Buildings with plans made to grant the Ministry power to commandeer obsolete property of all descriptions.[23] With a view to conserving raw materials, manufacture of a large list of items from steel was restricted, including metal windows, beds, springs, furniture, buttons, buckles, and sundry manufactures.[24] In the production of pig iron less scrap was employed in blast furnaces because of an increased use of home-produced iron ores.

IRON ORE, PIG IRON, FERRO-ALLOYS, AND STEEL

By Norwood B. Melcher [1]

SUMMARY OUTLINE

GENERAL FEATURES IN 1941

The domestic steel industry operated at record levels throughout 1941. Production was maintained at a rate well above 90 percent, in spite of the fact that the capacity increased considerably. The average operating rate for the entire year was 97.3 percent, and 82,839,259 net tons of steel were produced. This great activity in steel manufacture was reflected in the iron ore and pig iron industries during 1941. Domestic production of pig iron, exclusive of ferro-alloys, increased 19 percent over 1940 and established a new record of 55,085,446 net tons—an increase of 18 percent over the previous peak year 1929. Iron ore, exclusive of ore containing 5 percent or more manganese, likewise experienced a record year in 1941, and a total of 92,409,579 gross tons was mined—an increase of 25 percent over 1940 and 23 percent more than in the previous peak year 1917. However, iron ore is an essential raw material in our great war-production drive, and 1941 is not expected to retain its laurels long. If announced objectives are reached, iron-ore production in 1942 should easily pass the 100,000,000-ton mark; and steel production of 85,000,000 tons and a considerable increase in pig-iron output are anticipated.

[1] Includes a small quantity of ore produced in southern Wisconsin.
[2] Figures not available.
[3] Includes a small quantity of ore produced in southern Minnesota.
[4] Texas included with Southeastern and Southwestern districts in 1940 and included in Western in 1941.
[5] Some underground included with open pit.
[6] Small quantity of hematite included with magnetite.
[7] Small quantity of magnetite included with hematite.
[8] Small quantity of brown ore included with magnetite.
[9] Figures cover January–September, inclusive.
[10] Figures not available for publication.

Figure 1 shows the trends in domestic production of iron ore, pig iron, and steel since 1880.

Steel-consuming industries.—The automobile industry, although called upon to convert to war production during the latter months of the year, ranked second only to the construction industry in the consumption of steel during 1941. The production of automobiles in 1941 increased 8 percent over 1940 and totaled 4,838,561 units, which was only slightly below the 5-million-car year 1929. The automobile and aircraft industries consumed 6,392,202 net tons (10.2 percent) of the total (62,484,162 tons) consumed and exported. The construction industry experienced great activity during the year, using 8,127,889 tons or 13.0 percent of the total. The additions to arms-

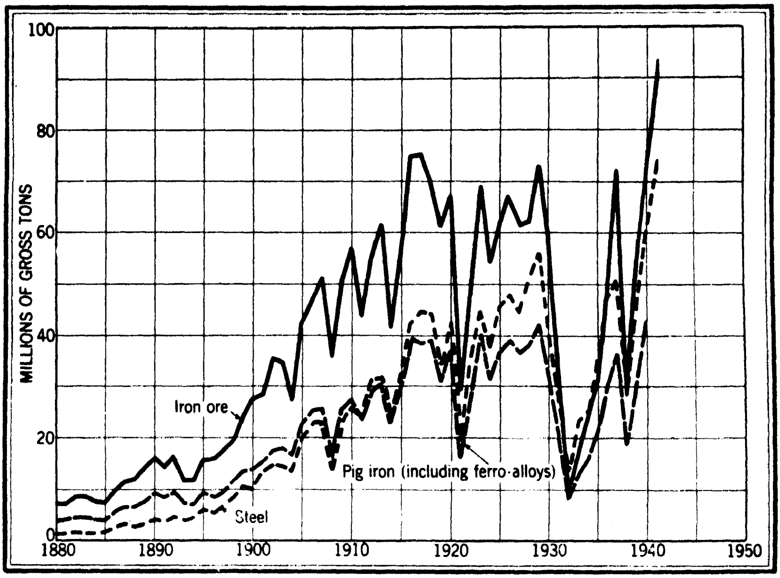

FIGURE 1.—Trends in production of iron ore, pig iron, and steel in the United States, 1880–1941.

production capacity during 1941 were almost exclusively in the form of new plants rather than the conversion of existing facilities.

The large volume of capital in hands of consumers made available through the increased output of steel was instrumental in raising the Nation's purchasing power to high levels. Consumers' demands were directed particularly to durable goods; in consequence, these articles were produced in extraordinary quantity during the first 9 months of the year. In the final months, shortages of raw materials forced curtailment in output of private consumers' goods. By the beginning of 1942, the new military program pointed to virtual elimination of all such production through control over uses of materials and conversion of whole industries to war production.

The farm-machinery industry had a record year in 1941. The industry was granted favorable priority for raw materials and drew heavily on steel products. Output of railroad cars—another major type of equipment—was hampered during much of 1941 by shortage of materials, especially steel plates. Production was 65,317 cars (not includ-

ing output of private car shops), about one-third more than in 1940, but this was far short of needs. Approximately 993 locomotives were built compared with 646 in 1940, and output trended toward Diesel and Diesel-electric units. The most dramatic advance in output during the year appeared in certain industries engaged directly in manufacturing finished arms. In the first stages of the armament program, emphasis was placed on planes and ships as the most urgently needed types of war materials, and it was in these arms categories that heaviest volume production was achieved by the year end. The number of naval ships completed during the year is not published, but deliveries of merchant tonnage aggregating 749,000 gross tons were almost 70 percent more than the 445,000 gross tons completed in 1940. Output of airplanes averaged more than 1,500 monthly (using only 9 months' figures) compared with 500 units a month average in the preceding year. However, these figures are dwarfed by the goal of 60,000 fighting planes and 8,000,000 dead-weight tons of merchant shipping set by the President early in 1942 to be produced before the end of this year.

The following table shows the distribution of steel to consuming industries during 1941.

Distribution of steel to consuming industries in 1941 [1]

	Net tons	Percent of total
Steel converting and processing industries:		
Wire drawers and wire product manufacturers	535,741	
Bolt, nut, and rivet manufacturers	1,160,767	
Forging manufacturers	1,144,442	
All other steel plants and foundries	1,956,853	
Total	4,797,803	7.7
Jobbers, dealers and distributors:		
Oil and natural-gas industry	1,018,371	
All other	8,181,440	
Total	9,199,811	14.7
Construction industry:		
Public (municipal, State, national)	518,555	
Highways	708,613	
Railways	102,494	
Automotive and aircraft	406,463	
Utilities	515,003	
Building trim, accessories and builders' hardware	1,020,109	
All other	4,856,652	
Total	8,127,889	13 0
Shipbuilding industry	2,733,413	4.4
Pressing, forming and stamping industry.		
Metal furniture and office equipment	676,944	
Hardware and household equipment	1,746,810	
All other	3,897,782	
Total	6,321,536	10.1
Container industry:		
Oil and natural-gas industry	437,367	
All other	4,052,043	
Total	4,489,410	7.2
Agricultural, including implement and equipment manufacturers	1,153,678	1.8
Machinery and tools:		
Machinery and tools, excluding electrical equipment	1,569,712	
Electrical machinery and equipment	1,301,275	
Total	2,870,987	4.6
Automotive and aircraft industry	6,392,202	10.2

[1] American Iron and Steel Institute.

Distribution of steel to consuming industries in 1941—Continued

	Net tons	Percent of total
Railroad industry:		
All railroads	3,533,866	
Car and locomotive builders and parts manufacturers	2,146,935	
Total	5,680,801	9.1
Oil, natural-gas, and mining industry:		
Oil and natural gas, including pipe lines	1,735,983	
Mining, quarrying, and lumbering	249,157	
Total	1,985,140	3.2
Miscellaneous industries and export	8,731,492	14.0
Total	62,484,162	100.0

Prices.—The composite price of finished steel, as compiled by Iron Age, remained constant at 2.30467 cents (revised figure) a pound throughout 1940 and 1941. Prices of No. 1 Heavy-Melting scrap at Pittsburgh started at $19.76 a net ton in January, dropped to $18.75 in February, and beginning in May remained at $17.86, the price maximum set by the Office of Price Administration. Pig iron held at $20.94 a net ton during January and February, rose to $21.01 in March, and remained thereafter at $21.08, the composite maximum price.

The price of ferromanganese at seaboard was held by maximum price regulation at $107.14 a net ton throughout 1941. Spiegeleisen, as quoted by Steel, continued at $32.14 a ton during the year. Prices of Lake ores have remained constant since April 17, 1940.

Figure 2 gives trends in prices of iron ore, pig iron, steel and steel scrap since 1890.

Employment and wages.—According to the American Iron and Steel Institute, steel pay rolls totaled $1,301,000,000 in 1941 compared with $961,000,000 in 1940 and only $841,000,000 in 1929. Hourly wages in 1941 averaged 95.9 cents an hour compared with 85 cents in 1940. Employment rose 86,000 during the year to a record total of 633,000. During 1941, steel workers averaged 38.6 hours a week. Total employment in all industries (excluding the armed forces) rose to 49.5 million in December 1941. In all, about 3 million were added to the employment list during the year. The real income of workers increased during 1941 despite higher living costs. An increase in hours worked a week and in wage rates during the year was accompanied by a marked increase in the number of industrial disputes.

Meeting demand for steel.—During 1941, domestic steel capacity was increased 4,418,000 net tons to a record total of 88,570,000 tons. Since January 1940 steel capacity has increased 6,950,000 tons, almost equal to Japan's total 1940 production of 7,100,000 tons.

The increase in open-hearth capacity was 3,542,000 tons and in electric furnace capacity 1,151,000 tons, whereas bessemer-steel capacity declined from 6,997,000 tons to 6,721,000 tons.

Blast-furnace capacity increased 2,784,000 tons during 1941 to a record total of 60,394,000 net tons. This capacity was made possible by the addition of five new blast furnaces and the return to service of five furnaces that had been long idle.

United States Government regulations regarding expansion of iron and steel capacity are promulgated by the Iron and Steel Industrial Branch, Division of Materials, War Production Board. The Division of Materials was set up as an operating division in the Office of Production Management by the O. P. M. Council on September 4, 1941, with the approval of the President. It represents an amalgamation of certain commodity sections (of which iron and steel is one) of the Production and Priorities Division, dealing with industrial materials.

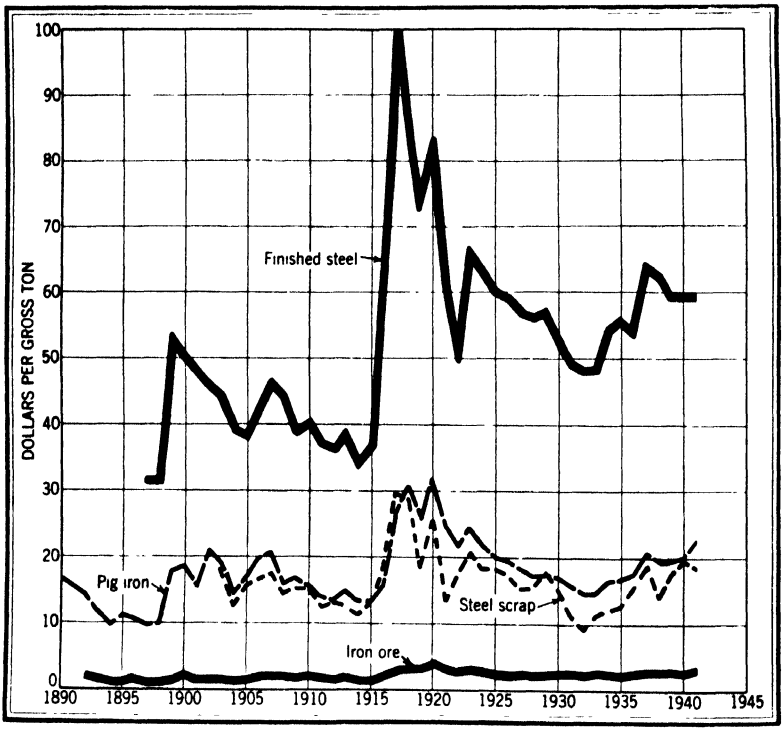

FIGURE 2.—Trends in prices of iron ore, pig iron, finished steel, and steel scrap, 1890–1941 The prices of iron ore and pig iron are the averages f. o. b. mines and furnaces, respectively, as reported to the Bureau of Mines; the price of finished steel is an average composite computed by American Metal Market; that of steel scrap is an average at Pittsburgh of No 1 Heavy Melting, computed by Iron Age.

Functions of the Division of Materials in the War Production Board are virtually unchanged from those it held in the Office of Production Management. The War Production Board was established January 16, 1942.

In fulfilling its functions, the branch formulates policies and recommends means for expanding and developing domestic sources, for purchasing, stock-piling, and assuring as great a supply of raw materials as possible, and for expediting production of iron and steel.

Foreign trade.—Because of war-time censorship, imports and exports for only 9 months of 1941 may be shown.

Statistics relating to imports and exports for 9 months of 1941 may be found under discussion of foreign trade in iron ore, pig iron, ferroalloys, and steel.

CONSUMPTION OF FERROUS SCRAP AND PIG IRON

Data on the consumption of ferrous scrap and pig iron, formerly included in this chapter, will be found in the chapter on Iron and Steel Scrap. Data on the consumption of pig iron will be found n the pig-iron section of this chapter.

IRON ORE

PRODUCTION AND SHIPMENTS

Iron-ore mining in the United States experienced its best year on record during 1941. Production totaled 92,409,579 gross tons—a gain of 25 percent over 1940. Output in 1941 came from 276 [2] mines, of which 18 produced more than 1 million tons each compared with 230 [2] mines and 15 in the million-ton class in 1940. Twenty States were active producers in 1941 compared with 19 in 1940. Minnesota, with 62,750,907 tons, supplied 68 percent of the domestic total; and Michigan, with 14,671,192 tons or 16 percent, was the second-largest producer. These two States and mines in Wisconsin (1,436,233 tons or 2 percent) constitute the Lake Superior region, which supplied 85 percent of the domestic total. The ratio of open-pit to underground production remained about the same in 1941; approximately two-thirds of the output in both years came from open-pit operations.

Iron ore mined in the United States in 1941, by States and varieties, in gross tons

[Exclusive of ore containing 5 percent or more manganese]

State	Number of active mines	Hematite	Brown ore	Magnetite	Carbonate	Total
Alabama	[1] 76	6,791,237	1,093,614			7,884,851

Total: 1941	[1] 276	[2] 86,725,406	1,366,849	[3] 4,316,718	606	92,409,579
1940	[1] 230	[3] 68,869,837	[4] 934,625	[3,4] 3,890,924	513	73,695,899

[1] Excludes an undetermined number of small pits. Output of these pits included in tonnage given.
[2] Small quantity of magnetite included with hematite.
[3] Small quantity hematite included with magnetite.
[4] Small quantity of brown ore included with magnetite.

[2] This figure does not include an undetermined number of small mines whose aggregate output is only a fraction of 1 percent of the total.

Shipments of iron ore likewise were much larger in 1941, amounting to 93,053,994 gross tons—an increase of 24 percent over 1940. The greater part of the iron ore mined in the United States is employed in the manufacture of iron and steel, but 99,480 tons of domestic ore were shipped in 1941 for other uses, as follows: Cement, 57,133 tons; paint, 20,792 tons; ferromagnesite, 6,000 tons; flux at nonferrous smelters, 1,795 tons; and other industries, 13,760 tons.

The quantities of iron ore in the following tables include ore that was beneficiated—that is, treated in any way to improve the ore content—as well as ore that did not require treatment.

Although included in the figures on production, the iron ore sold for the manufacture of paint—20,792 tons in 1941 valued at $101,710 ($4.89 a ton) compared with 8,912 tons in 1940 valued at $45,578 ($5.11 a ton)—is not included in shipments from mines. The output of manganiferous ore that contained 5 to 35 percent manganese also is excluded. Moreover, the statistics do not include iron sinter recovered from the roasting of domestic pyrite concentrates in Tennessee.

PRINCIPAL MINES

The importance of large operations in the iron-mining industry is shown by the fact that 18 units yielding more than 1,000,000 tons each produced 56 percent of the entire output in 1941. Of the 18 million-ton producers in 1941, 13 are in Minnesota (all on the Mesabi range), 2 in Alabama, 1 each in Pennsylvania and Wisconsin, and 1 in Michigan. Of the 18 principal producers in 1941, 11 were open-pit operations, 4 were operated by underground methods, and 3 were combinations. Except for 1 mine that produced magnetite, all the principal mines produced hematite.

Grand total of United States (276 [2] mines)					92,409,579

[1] 1 mine producing between 300,000 and 400,000 tons included with those producing more than 500,000 tons.

[2] Excludes an undetermined number of small pits The output of these pits is included in the tonnage given

BENEFICIATION

Beneficiation of iron ore was reported at 112 mines in 8 States in 1941 compared with 70 mines in 8 States in 1940. At many mines the ore is crushed and screened to improve its structure, but ore so improved is not included in the statistics on beneficiated ore. Some iron ore is recovered as dust from blast furnaces; data on ore so re-

covered, however, have been accounted for previously in shipments from mines.

Beneficiated ore shipped from domestic mines in 1941 increased 50 percent over 1940 and comprised 21 percent of the total shipments compared with 17 percent in 1940.

Beneficiated iron ore shipped from mines in the United States, 1940–41

[Exclusive of ore containing 5 percent or more manganese and of ore sold for paint]

State	Variety	1940		1941	
		Gross tons	Value	Gross tons	Value
Alabama	Brown ore	750,131	$1,792,584	1,230,892	$3,273,354
Georgia	do	41,015	63,353	245,972	572,361

New York Pennsylvania	do do	2,149,197	8,569,580	2,375,123	10,017,684
Tennessee Texas	Brown ore do	27,879	91,164		
California	Magnetite			10,684	50,940
		12,925,741	37,173,590	19,376,120	55,834,894

The quantity of crude ore beneficiated in the Lake Superior district (all in Minnesota) in 1941 totaled 25,691,501 gross tons and the beneficiated ore recovered 15,125,368 tons—a ratio of 1.699 : 1. In 1940 the crude ore treated totaled 14,547,504 tons and the beneficiated ore recovered therefrom 9,439,921 tons—a ratio of 1.541 : 1. Most of the concentration in this district is done by washing, but a few plants are equipped with jigs, and two plants sinter ore after washing. Processes have been described by Counselman.[4]

In the past, an increase in domestic iron-ore production has been accompanied by a percentage decrease in the quantity of beneficiated ore shipped. However, in the record year 1941, 21 percent of the shipments were beneficiated ore compared with 17 percent in 1940. Thus it is apparent that supplies of direct shipping ores are being stressed to the limit, and lower-grade deposits are being exploited. This is made possible in part by more efficient mining and beneficiating methods. Data showing the relationship between beneficiated ore and total shipments for recent years are shown in the following table, and corresponding statistics for 1914 (the first year for which they were gathered) to 1929 are given in Mineral Resources, 1930, part 1. Data for 1930 to 1934, inclusive, are given in Minerals Yearbook, 1935, and for 1932 to 1936, inclusive, in Minerals Yearbook, 1937.

Iron ore shipped from mines in the United States, 1925–29 (average) and 1937–41, in gross tons, and percentage of beneficiated ore compared to the total shipped

[Exclusive of ore containing 5 percent or more manganese and of ore sold for paint]

Year	Beneficiated	Total	Proportion of beneficiated to total (percent)	Year	Beneficiated	Total	Proportion of beneficiated to total (percent)
1925–29 (av.)	8,653,590	66,697,126	13 0	1939	9,425,809	54,827,100	17 2

AVERAGE VALUE

The average value per gross ton of iron ore at the mines was $2.68 in 1941 compared with $2.51 in 1940.

The table that follows gives the average value at the mines of the different classes of iron ore in 1940–41 for each of the producing States or groups of States, except where there are fewer than three shippers of a certain variety of ore in a State and permission was not given to publish the value. These data are taken directly from statements of producers and probably represent the commercial selling prices only approximately, as not all reports are comparable. Some evidently include mining costs only; others contain, in addition, the cost of selling and insuring the ore; others include an allowance for a sinking fund; and still others comprise only costs charged against blast furnaces. None of the reports, however, is supposed to include freight charges.

Average value per gross ton of iron ore at mines in the United States, 1940–41

CONSUMPTION

The production of 55,085,446 net tons of pig iron in 1941 required 94,404,667 net tons of iron ore and manganiferous iron ores, 6,858,576 tons of mill cinder and roll scale, and 1,317,072 tons of purchased scrap, an average of 1.862 tons of metalliferous materials (exclusive of home scrap and flue dust) per ton of iron made.

The greater part of the iron ore used in Alabama furnaces in 1941 was hematite, chiefly from mines in Jefferson County, but some hematite came from De Kalb, Cherokee, and St. Clair Counties. Brown ore, iron sinter, pyrite ash, imported iron ore, manganese ore, and small quantities of domestic manganese-bearing ores were used. The brown ore originated chiefly in mines of the Birmingham and Russellville districts, Alabama, and the Chattanooga district, Georgia. In addition to iron sinter (sintered pyrite ash) from Tennessee, pyrite ash was shipped to Birmingham in 1940 from acid plants in other Southern States. The pyrite from which this ash was made came from both domestic and foreign ores. The domestic manganese-bearing ores came chiefly from Arkansas, Georgia, and Tennessee. Imported

manganese-bearing ores came from Cuba. In 1941, Alabama furnaces consumed an average of 2.450 tons of ore in making 1 ton of pig iron—the highest average for any State.

Maryland furnaces consumed considerable domestic ore in 1941, in addition to ores from Africa, Brazil, Chile, and Cuba. These furnaces used an average of 1.597 tons of ore per ton of pig iron; however, they used proportionately more cinder, scale, and scrap than any other State.

Blast furnaces in Illinois, Indiana, Kentucky, Michigan, Minnesota, and West Virginia handled Lake Superior iron ore and manganiferous iron ore almost exclusively. Furnaces in Kentucky had the lowest consumption of metal-bearing material per ton of iron.

In New York the furnaces in the Buffalo district used ore chiefly from the Lake Superior district, magnetite from New York, and some manganese ore from Cuba, and the furnace at Troy consumed magnetite from the Chateaugay mine at Lyon Mountain, N. Y.

Blast furnaces in Ohio consumed magnetite from New York and hematite and brown ore from Missouri, in addition to ore from the Lake Superior district.

Virtually all the ore consumed in western Pennsylvania furnaces came from the Lake Superior district. Those in the eastern part of the State used some Lake ore; magnetite ores from Pennsylvania, New Jersey, and New York; and some ore from Africa, Australia, Chile, Cuba, and Spain.

The Pueblo (Colo.) blast furnaces consumed hematite from the Sunrise mine in Wyoming and manganese-bearing ores, chiefly from Colorado, New Mexico, and California.

The Provo (Utah) furnace treated chiefly semialtered magnetite from the Iron Mountain mine near Cedar City, Utah, manganese tailings from Montana, and manganese-bearing ores from Nevada, Idaho, and Utah.

The Tennessee furnace used chiefly Tennessee brown ore and iron sinter.

Iron ore and other metallic materials consumed and pig iron produced in 1941, by States, in net tons

State	Metalliferous materials consumed				Pig iron produced, exclusive of ferro-alloys	Materials consumed per ton of iron made

FOREIGN TRADE

Imports for consumption of iron ore for only the first 9 months of 1941 are available for publication. During that period, Chile was the chief source of iron ore imported into this country, furnishing 73 percent of the total; Canada supplied 12, Cuba 8, and Brazil 5 percent. In addition to the figures in the following table, 22,439 tons of dross or pyrite ash were imported from Canada during the first 9 months of 1941.

Iron ore imported for consumption in the United States, 1939–41, by countries, in gross tons

Country	1939		1940		1941 (Jan.-Sept.)	
	Gross tons	Value	Gross tons	Value	Gross tons	Value

Exports of iron ore from the United States totaled 1,347,641 gross tons valued at $4,362,806 ($3.24 a ton) during the first 9 months of 1941. Exports for the full year 1940 totaled 1,386,304 gross tons valued at $4,624,555 ($3,34 a ton).

MINING IN CUBA

Shipments from Cuban mines decreased 5 percent in 1941 from 1940. The 1941 total (200,350 gross tons) included 73,308 tons of hematite carrying (dried) 56.17 percent iron, and 84,396 tons of siliceous ore carrying (dried) 30.34 percent iron, from the Daiquiri-Juragua mines on the southern coast, and 42,646 tons of nodulized brown ore carrying (dried) 55.69 percent iron from the Mayari district near the northern coast. The Mayari mine resumed operations in 1941.

The total stock of ore reported on hand was 90,930 gross tons at the end of the year compared with 111,797 tons at the end of 1940.

The following table shows shipments of iron ore from Cuba since the mines were opened in 1884. The statistics on shipments of Cuban iron ore are collected by the Bureau of Mines.

Iron ore shipped from mines in the Province of Oriente, Cuba, 1884–1941, in gross tons

Year	Juragua (hematite and magnetite), Daiquiri (hematite and a little magnetite)	Sigua (hematite)	Mayari (brown ore)	Guamá (hematite)	El Cuero (hematite)	Total
1884–1939	[1]22, 162, 124	20, 438	3, 901, 183	41, 241	903, 103	27, 028, 089

[1] Of this quantity, 5,932 tons were sent to Pictou, Nova Scotia, and 64,228 tons to other ports outside of the United States.

REVIEW OF LAKE SUPERIOR DISTRICT

Production and shipments.—Operations in the Lake Superior district (the principal producing district) were conducted at record levels during 1941. The Lake shipments broke many records during 1941 and moved 79,654,785 gross tons of iron ore and manganese-bearing ore from United States ports. The season had the earliest opening (April 8) in 40 years, and 6,918,914 tons were shipped during April compared with 464,669 in April 1940. The quantity shipped increased every month to August, when record shipments of 11,429,569 gross tons were made. Likewise, a favorable late closing date (December 8) permitted shipments of 822,998 tons in December.

Eighty-five percent of the United States total iron-ore production came from the Lake Superior district in 1941, and all shipping facilities were strained to the limit. In July Canadian vessels entered the American ore trade to assist in shipping the year's record tonnage. Total shipments of ore by water and all-rail from the Lake Superior district were 80,748,454 gross tons (79,563,286 tons of iron ore and 1,185,168 tons of manganese-bearing ores containing 5 percent or

more manganese) compared with 63,949,536 tons (62,884,545 tons of iron ore and 1,064,991 tons of manganese-bearing ore containing 5 percent or more manganese) in 1940. The iron-ore-shipment figures given above include 47 tons of iron ore from Fillmore County, Minn., which is outside the true Lake Superior district.

Production in the Lake Superior region in 1941 increased 28 percent over 1940, to establish an all-time record. The 85 percent of the United States total contributed by the district in 1941 compares with 83 percent in 1940 and 81 percent in 1939. It is therefore apparent that as domestic iron-ore-mining activity increases, the bulk of the increase is supplied from the Lake Superior region. Several ranges contributed to the district total. The Mesabi was the largest producer, furnishing 76 percent of the district and 65 percent of the United States total. The output, by ranges, is listed in the following table. After 1905 figures do not include manganiferous iron ore containing 5 percent or more manganese.

Iron ore mined in the Lake Superior district, 1854–1941, by ranges, in gross tons

[Exclusive after 1905 of ore containing 5 percent or more manganese]

Year	Marquette	Menominee	Gogebic	Vermilion	Mesabi	Cuyuna	Total
1854–1939	201,533,822	184,770,564	213,782,729	67,135,407	1,073,242,695	26,056,086	1,766,521,303
1940	5,284,194	2,679,364	5,770,357	1,531,963	45,483,450	721,397	61,470,725
1941	6,230,612	3,822,451	6,054,362	1,853,030	59,688,047	1,209,783	78,858,285
	213,048,628	191,272,379	225,607,448	70,520,400	1,178,414,192	27,987,266	1,906,850,313

In 1941, 76 percent of the ores produced on the iron ranges of the Lake Superior district came from open-pit mines. A large part of the open-pit production originates in the Mesabi range, which in 1941 supplied 96 percent of the open-pit ore mined in the district. There is no open-pit mining in northern Wisconsin and relatively little in Michigan. In addition to the output on the Mesabi range, there is some open-pit production in Minnesota on the Cuyuna and Vermilion ranges.

Holt [5] has described the progress made in the mining industry of Minnesota during the last few years. Open pits, which were not feasible in the past, are now being developed, because of the rapid improvement in stripping and mining methods. The work formerly required in constructing railroad tracks, building, and dump trestles has been eliminated in favor of the speedy and efficient method of using trucks and bulldozers for stripping and hauling.

Most stripping is done in winter in order to spread out labor requirements over the entire year and to utilize equipment that otherwise would be idle. The newer equipment now available is built for work in extreme cold and heat. Overburden is loaded by electric, Diesel, or gasoline shovels and a few steam shovels. The larger pits still use locomotives and side-dump stripping cars, but truck haulage is replacing steam locomotives to a greater extent each year. After the overburden has been removed, virtually all ores require drilling and blasting before loading. Most drilling is done with a churn-type drill,

[5] Holt, Grover J., Mining Practice and Mine Transportation on Minnesota's Iron Ranges: Regional Meeting, Am. Inst. Min. and Met. Eng., Duluth, Minn., August 12–15, 1941, pp. 10–14.

although recently a new type of large-diameter auger has been used successfully for drilling horizontal holes.

The most important development in mining in recent years has been the radical change in the methods of transporting open-pit ore. In many pits the change to trucks, tractors, bulldozers and belt-conveyor systems has necessitated replacing tracks, locomotive repair shops, and locomotive engineers with roads, garages, drivers, and mechanics. Locomotive cranes are being replaced by cranes mounted on treads and trucks.

Shipments from the Michipicoten range in Ontario, Canada, continued during 1941. Although this output is not included in Bureau of Mines production figures, it enters the same commercial channels. The ore comes from the old Helen mine of the Algoma Steel Corporation, which in August 1939 began to produce from new open-pit operations and made shipments for the first time since 1922. A total of 462,747 tons of sinter, made from the carbonate ores, was shipped during the season, compared with 361,394 tons in 1940.

Analyses.—The following table, compiled by the Lake Superior Iron Ore Association, summarizes the average analyses of the total tonnages of all grades of ore shipped and shows the remarkable uniformity maintained during the past 5 years. This uniformity does not mean, of course, that the average grade of available Lake Superior ore is not declining. The grade of shipments has been maintained partly by beneficiation and partly by mixing ores from different deposits. The method of sampling and grading Lake Superior iron ores has been described by Bayer,[6] and the method of classification and sampling by Murray.[7]

Average analyses of total tonnages (bill-of-lading weights) of all grades of iron ore from all ranges of Lake Superior district, 1937–41

Year	Gross tons	Iron (natural)	Phosphorus	Silica	Manganese	Moisture
		Percent	*Percent*	*Percent*	*Percent*	*Percent*
1937	61,972,823	51.53	0.091	8.27	0.82	11.31
1938	19,353,497	51.90	.089	8.25	.81	10.13
1939	44,983,754	51.75	.085	8.27	.76	10.73
1940	63,308,413	52.09	.085	8.00	.77	10.93
1941	79,941,240	51.83	.085	8.18	.78	11.01

Stocks at Lake Erie ports.—At the close of navigation in 1941 according to the Lake Superior Iron Ore Association, 5,290,117 gross tons were in stock at Lake Erie ports compared with 4,786,643 tons on the corresponding date in 1940. At the opening of navigation in May 1942, 2,529,175 tons were in stock at these ports—an increase of 594,106 tons from the figure on May 1, 1941. Withdrawals from docks were therefore 2,760,942 tons during the winter of 1941–42.

Prices of Lake Superior ore.—The prices established April 17, 1941, for the four standard grades of Lake Superior ore were unchanged from a year ago and remained 5 cents a ton lower than the price maintained from 1926 to 1939. Beginning April 17, 1940, the unit

[6] Bayer, E. P., Sampling and Grading Mesabi Iron Ore: Min. and Met., vol. 18, No. 372, December 1937, pp. 547–548. Grading Lake Superior Iron Ores: Eng. and Min. Jour., vol. 139, No. 3, March 1938, pp. 50–51.

[7] Murray, C. B., Classification and Sampling; Lake Superior Iron Ores (chap. 4). Lake Superior Iron Ore Assoc., Cleveland, 1938, pp. 69–72.

prices for base ore of the various grades quoted at Lake Erie ports were as follows: Old-Range Bessemer, 9.223 cents; Mesabi Bessemer, 8.932 cents; Old-Range Nonbessemer, 8.932 cents; and Mesabi Nonbessemer, 8.641 cents, respectively, $4.75, $4.60, $4.60, and $4.45 a gross ton. The base of the four standard grades for 1925–41 is an iron content of 51.5 percent natural. For the bessemer grades, the allowable phosphorus content is 0.045 percent (dry), and for the nonbessemer grades the phosphorus content ranges from 0.045 to 0.18 percent. Ores containing more than 0.18 percent phosphorus are classed as high-phosphorus ores, whereas those containing 18 percent or more silica are classed as siliceous ores.

Reserves.—Estimates of ore reserves for Minnesota, furnished by the Minnesota Tax Commission, and for Michigan, furnished by the Michigan Board of Tax Commissioners, are shown in the following tables. These estimates reveal decreases from 1940 of 24,796,880 gross tons in Minnesota and 1,315,899 tons in Michigan. Reserves in Wisconsin have been estimated recently at 5,500,000 tons.

Unmined iron-ore reserves in Minnesota, May 1, 1937–41, in gross tons

Range	1937	1938	1939	1940	1941
Mesabi	1,173,108,376	1,150,817,768	1,132,513,348	1,122,593,126	1,097,000,026
Vermilion	13,943,325	14,274,025	13,631,484	13,208,699	14,018,934

MINING BY STATES

Alabama.—Production of iron ore in Alabama during 1941 increased 8 percent over 1940 and established a new record. About 85 percent of the 1941 production came from underground operations compared with 89 percent in 1940, indicating a considerable increase in open-pit production during 1941. Consequently, brown-ore production increased 42 percent in 1941. Hematite, which comprised 86 percent of the State total in 1941, is derived chiefly from underground operations on Red Mountain near Birmingham in Jefferson County, where Raimund Nos. 1 and 2, Red Mountain group (comprising the Muscoda, Wenonah, and Ishkooda groups), Ruffner, Sloss Nos. 1 and 2, Spaulding, and Woodward No. 3 mines were producers. Several smaller mines (open-pit and underground) in Cherokee, De Kalb, St. Clair, and Jefferson Counties contributed to the total output of hematite ore. The hematite produced in 1941 averaged (natural) 35.57 percent iron, 0.15 percent manganese, 0.32 percent phosphorus, and 15.02

percent lime. The Red Mountain group, with 4,056,217 tons, was the third-largest producer in the United States in 1941. Limonite (brown ore) is mined from a number of widely scattered deposits in Alabama, but production is not nearly as large as that of red ore. In 1941, the output of brown ore constituted 14 percent of the Alabama total. Brown ores, however, are higher-grade and usually have been beneficiated, although some operations are rather crude. The brown ore mined in 1941 averaged (natural) 47 percent iron and 0.77 percent manganese. Brown ore is mined from open-cuts and was produced chiefly from the Tecumseh mine in Cherokee County, the Russellville and Parish mines in Franklin County, and the Martaban and Reno mines in Tuscaloosa County.

California.—Production of iron ore in California increased from 1,071 tons in 1940 to 53,531 tons in 1941. Most of the ore was hematite used for cement. The ore mined averaged 55 percent iron during 1941.

Connecticut.—A small quantity of brown iron ore came from the Ore Hill mine in Litchfield County during 1941. This ore was used as a foundry flux and was the first iron ore reported from Connecticut since 1920.

Georgia.—The heavy demand for iron ore in the South enabled production of iron ore in Georgia to continue to increase in 1941. Production consisted of 21,313 tons of hematite and 239,354 tons of brown ore compared with 7,163 tons of hematite and 94,123 tons of brown ore in 1940. Virtually all the brown ore mined during 1941 was beneficiated. The iron ore from Georgia averaged (natural) 46.91 percent iron. The average value at the mines was $2.61 for hematite and $2.29 for brown ore compared with $2.24 and $1.79, respectively, in 1940.

Michigan.—Output from Michigan comes from three ranges—the Marquette, the Menominee, and the Gogebic. All ranges increased their production in 1941, the Menominee showing the largest gain in tonnage. Production in Michigan rose 18 percent in 1941 over 1940 and totaled 14,671,192 gross tons. Of this total, 88 percent came from underground mines; the Negaunee mine—an underground producer on the Marquette range—was the largest producer. The iron content (natural) of the ore mined in Michigan in 1941 averaged 51.68 percent compared with 52.03 percent in 1940. Iron-ore reserves in Michigan at the end of 1941 totaled 134,509,732 gross tons—a decrease of 1,315,899 tons during the year.

A report of the iron-ore mines of Michigan for 1941, published by the Geological Survey Division of the Michigan Department of Conservation,[8] shows that the average number of men employed was 7,553 (6,743 in 1940), the average number of days worked 248 (213 in 1940), the average daily wage $7.60 ($7.48 in 1940), the average yearly earning $1,875.79 ($1,593.82 in 1940), and the average tons of ore mined per man per day 7.15 (5.10 in 1940).

The data in the following table on average per-ton costs of mining ore at underground mines and at siliceous open pits have been abstracted from statistics published in much greater detail by the Geological Survey Division of Michigan.

[8] Eddy, G. E., General Statistics Covering Costs and Production of Michigan Iron Mines. Michigan Dept. of Conservation, Geol. Survey Div., Lansing, 1942, 9 pp.

Average costs, per gross ton, of mining iron ore at underground mines and at siliceous open pits in Michigan in 1941

Item	Underground				Siliceous open pits
	Gogebic	Marquette	Dickinson and Iron	Total

Gross ore profit [1]	.3832	.6926	.5948	.5548	.1059

[1] This figure does not represent true profit, as much ore is sold below the Lake Erie price.

Minnesota.—In 1941, the output of iron ore in Minnesota increased 31 percent over that in 1940 and was 30 percent greater than the previous peak established in 1937. Three ranges contribute to Minnesota's production—the Cuyuna, the Mesabi, and the Vermilion. The Mesabi range supplied a large part of the Minnesota total and in 1941 produced 59,688,047 tons. The output from open-pit mines in 1941 furnished 93 percent of the total compared with 91 percent in 1940 and 88 percent in 1939. Of the 18 domestic mines producing more than 1 million tons each in 1941, 13 were in Minnesota; of these 11 were open pits, and 2 used combination open-pit and underground methods. Of the 102 mines in Minnesota active in 1941 (79 in 1940), 67 (52 in 1940) yielded more than 100,000 tons each. The iron content (natural) of the ore mined in 1941 averaged 52.43 percent compared with 52.36 percent in 1940.

According to the annual report of the mine inspector of St. Louis County, the average number of men employed in iron mines in the county was 7,097 in 1941 (5,547 in 1940), and the average daily wage was $7.02 ($6.70 in 1940) for 8 hours. In 1941, 8,065,960 cubic yards of overburden were removed compared with 2,728,306 in 1940.

According to the annual report of the mine inspector of Itasca County, the average number of men employed in iron mines in the county was 3,947 in 1941 (3,047 in 1940), and the average daily wage was $6.82 ($6.40 in 1940) for 8 hours. In 1941, 11,194,181 cubic yards of overburden were removed compared with 4,395,650 in 1940.

Unmined iron-ore reserves in Minnesota on May 1, 1941, totaled 1,176,031,225 gross tons, a decrease of 24,796,880 tons from 1940.

Missouri.—An undetermined number of small mines and pits in Bollinger, Butler, Carter, Crawford, Dent, Franklin, Madison, St. Francois, Washington, and Wayne Counties supplied the iron-ore output of Missouri in 1941, which decreased considerably from 53,638 tons in 1940 to 18,653 tons in 1941. The ore, which averaged 51.90 percent iron, comprised both hematite and brown ore, was mined by open-pit and underground methods, and was shipped to paint and steel plants as well as to nonferrous smelters.

Nevada.—Jay Jacobson produced the State total of 215 long tons from the Tom O'Shanter mine in Clark county. All was used as a flux in nonferrous smelters.

New Jersey.—The output of iron ore in New Jersey decreased 2 percent in 1941 from 1940 and totaled 649,374 tons. The ore, all magnetite and all from underground operations, came from three mines in Morris County and one mine in Warren County in the northern part of the State. New Jersey ores are crushed and concentrated before shipment. Most of the concentration is done magnetically, although some nonmagnetic martite is recovered by gravity methods, and some hand-sorting is practiced, principally to recover high-grade lump used in open-hearth steel furnaces. The concentrates produced in 1941 averaged (natural) 62.35 percent iron. The largest output came from the Scrub Oaks mine, which produced 798,751 gross tons of crude ore. Concentrates from this ore totaled 317,205 gross tons averaging 62.12 percent iron. Other producers were the Mount Hope, Richard, and Washington mines.

New York.—The iron ore produced in New York during 1941 was chiefly magnetite from underground operations at the Harmony and Old Bed shafts in Essex County and the Chateaugay mine in Clinton County. Some hematite was mined for paint in Oneida and Wayne Counties and a small amount for other coloring purposes in St. Lawrence County. Shipments from New York in 1941 included sinter, averaging 67 percent iron; lump, averaging 61 percent iron; and concentrates, averaging 68 percent iron.

The largest producer was the Republic Steel Corporation, which operates properties at Mineville (near Port Henry) and at Lyon Mountain.

Oklahoma.—The iron ore accredited to Oklahoma in 1941 came from two operations in Johnston County. All was brown ore and was used in the manufacture of cement.

Pennsylvania.—Pennsylvania is the most important source of magnetite in the United States. The output comes from the Cornwall mine in Lebanon County, where the ore is extracted by both open-pit and underground methods. The ore is shipped to Lebanon, Pa.. where it is concentrated magnetically. In addition, some carbonate ore for use in paint was mined in Carbon County in 1941, and some brown paint ore came from Clearfield County. Hickok [9] has summarized the history of iron-ore production in Pennsylvania and the changing economic conditions that affect the industry and control its history; he also discussed the geological environment, mode of origin, and future reserves of the various types of iron ore.

South Dakota.—Iron ore from South Dakota increased from 640 tons in 1940 to 2,150 tons in 1941. All was shipped for paint and was brown ore from the Hausle mine in Pennington County.

Tennessee.—No iron-ore production was reported from Tennessee in 1941. However, a considerable quantity of sintered pyrite ash was made at the plants of the Tennessee Copper Co. in Ducktown Basin. This sinter, which contained 67.5 to 69.4 percent iron and 0.005 percent phosphorus in 1941, moved largely to blast furnaces in Alabama and Tennessee. Such sinter is not included in iron-ore production or shipment figures for the United States.

Texas.—The output of iron ore from Texas came from the Linden mine in Cass County. The product is brown ore, which averaged 52.5 percent iron in 1941.

[9] Hickok, W. O., IV, Iron Ores of Pennsylvania Pennsylvania Geol. Survey Bull. M 18-B, 4th ser., 1939, 21 pp.

Utah.—Two operators in Iron County supplied the Utah total in 1941. By far the larger output came from the Iron Mountain mine, and a relatively small quantity came from the Great Western. The ore, principally semialtered magnetite, contained (natural) 54.47 percent iron and moved largely to the blast furnace at Provo, Utah, although small quantities went to steel plants.

Virginia.—A small production of 331 tons of brown ore came from the Oriskany mine in Botetourt County in 1941 and was shipped for the manufacture of hydrogen gas.

Washington.—Two underground mines, the Napoleon in Stevens County and the Keystone in Pend Oreille County, and an open-pit mine, the Neutral in Okanogan County, supplied the iron ore from Washington in 1941. The underground mines yielded hematite averaging about 27 percent iron, which was used in the manufacture of cement. The Neutral mine yielded magnetite averaging about 68 percent iron, which was used in making ferromagnesite.

Wisconsin.—The Montreal underground mine in Iron County was the largest producer of iron ore in Wisconsin, contributing 1,080,136 gross tons of the 1,436,233 produced in 1941. The ore—hematite—averaged (natural) 53.32 percent iron, 1.12 percent manganese, and 0.052 percent phosphorus. The Cary underground mine, also in Iron County, furnished 352,097 tons of hematite containing (natural) 53.21 percent iron, 1.26 percent manganese, and 0.054 percent phosphorus. In addition, 4,000 tons of ore were shipped from the Matilda mine in Florence County.

Wyoming.—The output of iron ore from Wyoming in 1941, all from the Sunrise mine, was 985,852 gross tons of hematite containing (dry) 55.11 percent iron, 0.08 percent manganese, 0.075 percent phosphorus, and 6.8 percent moisture. Much of the ore is a red, earthy hematite similar to Mesabi ore. Production came from both open-pit and underground operations.

MEN EMPLOYED AND OUTPUT PER MAN

Although complete information on employment at iron-ore mines in 1941 is not yet available, incomplete figures indicate that about 28,000 men working about 56,000,000 man-hours were required to produce 92,409,579 tons of merchantable ore—an average of about 1.7 tons per man-hour, an all-time record. Thus, the total man-hours worked in 1941 advanced 15 percent over 1940, whereas the output of merchantable ore increased 25 percent; in consequence, output per man-hour increased 13 percent. The gain in output per man-hour in

1941 compared with 1940 was due mainly to a further shift in the production of ore from underground to open-pit mines and to nearer-capacity operation of large units. Specifically about 71 percent of the output came from open-pit mines in 1941 compared with 67 percent in 1940, and 18 mines produced more than 1 million tons each in 1941 compared with 15 in 1940.

Figure 3 shows trends in employment and output at iron-ore mines in the United States from 1923 to 1940.

During 1940 (the latest year for which complete statistics are available) a substantial increase in iron-ore output resulted in increased employment at the mines. The average number of men increased, as did the average number of days and total man-hours worked. In 1940, 25,128 men working 48,731,997 man-hours produced 73,695,899

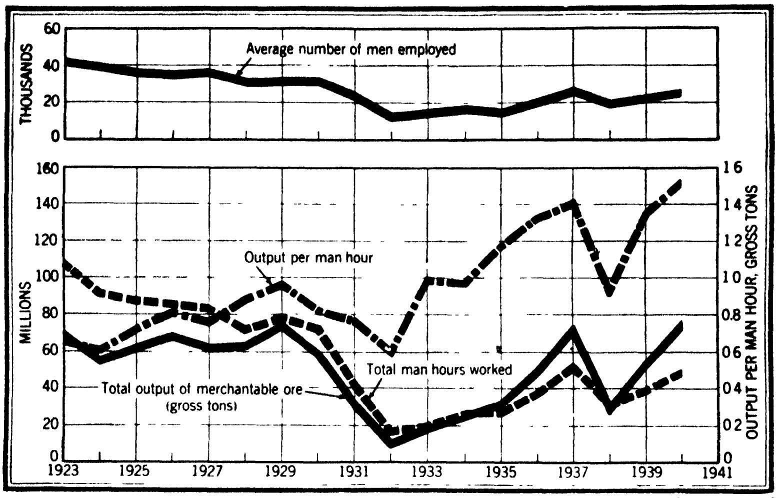

FIGURE 3.—Trends in number of men employed at iron-ore mines, output of merchantable ore, man-hours worked, and output per man-hour in the United States, 1923–40.

gross tons of merchantable ore—an average output of 1.512 tons per man-hour—whereas in 1939, 21,859 men working 39,055,362 man-hours produced 51,731,730 tons of merchantable ore—an average output of 1.325 tons per man-hour. Thus, although the average number of men employed increased 15 percent from 1939 to 1940 and the number of man-hours gained 25 percent, the output of merchantable ore advanced 42 percent, resulting in a 14-percent increase in the output per man-hour. The labor requirements in 1940 were relatively smaller than in 1939 due to several factors—the proportionately larger output of open-pit mines, nearer-capacity production of operating units, and the stripping of proportionately much less overburden in preparation for future mining.

In 1940 the number of man-hours of labor increased over 1939 in all districts, but the increases in the Lake Superior and Southeastern districts (24 and 25 percent, respectively) were relatively less than in the other chief producing districts. The increases in the Northeastern and Western districts were 26 and 33 percent, respectively. In the Lake Superior district, the output of merchantable ore per man-hour in 1940 reached 2.032 tons—18 percent more than in 1939 and 14 percent more than the previous record year of 1937. The large gain

(19,791,715 tons or 47 percent) in Lake Superior output in 1940 over 1939 required the employment of 16 percent more men. This, plus an 8-percent increase in the average number of days worked, resulted in a 24-percent rise in the number of man-hours worked. Much of the Lake Superior output comes from Minnesota, where open pits furnished 91 percent of the State total in 1940. Because of this pre-

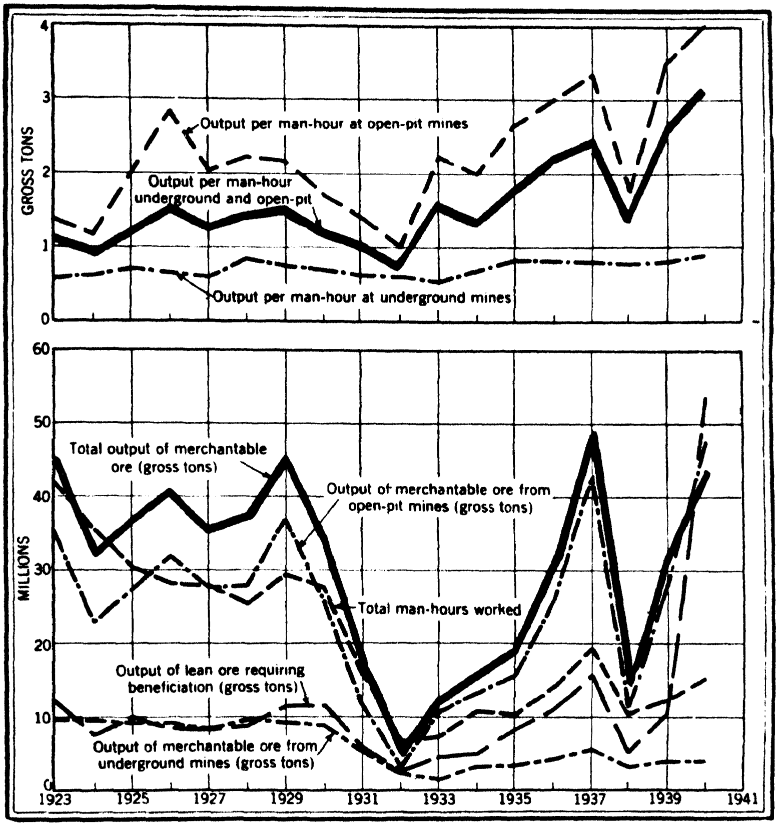

FIGURE 4.—Trends in output of merchantable iron ore per man-hour at open-pit mines in Minnesota compared with production of merchantable and lean ore and total man-hours worked, 1923–40.

ponderant production from open pits, the output per man-hour in Minnesota is greater than in any other State or district and in 1940 amounted to 3.136 tons—a 22-percent increase over 1939. Although advances in mechanization, more efficient mining methods, and better management of mines have done much to increase output in recent years, most of the gain is due to expansion of open-pit operations in Minnesota. For example, although about 75 percent of the merchantable ore output of Minnesota in 1923–32 came from open-pit mines, 85 percent was so produced in 1933–40. Minnesota contributed 61 percent of the total merchantable ore produced in 1923–40, and during this period the output at open-pit mines averaged 2.189 tons per man-hour compared with only 0.707 ton per man-hour at underground mines.

The greater output per man-hour in recent years also was due partly to the stripping of proportionately less overburden in Minne-

sota in 1933–40 than in 1923–32. In 1933–40 about one-fourth cubic yard of overburden was removed for each ton of merchantable ore mined in Itasca and St. Louis Counties, Minnesota, whereas in 1923–32 about one-half cubic yard of overburden was recovered for each ton of ore mined. Any material shift in the labor force used for direct mining of the ore at the expense of that used in stripping will result in a much higher output per man-hour for any year.

Another factor that affects the output per man-hour is the tendency to mine leaner ore. Proportionately more lean ore requiring beneficiation has been mined in Minnesota in recent years than in 1923–32. In 1933–40, for instance, beneficiated ore represented 21 percent of

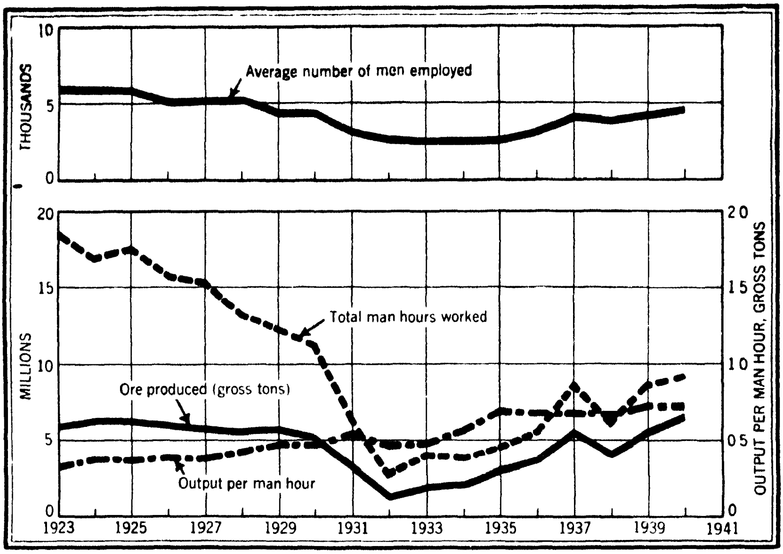

FIGURE 5.—Trends in production, man-hours worked, output per man-hour, and number of men employed at iron-ore mines in Jefferson County, Ala., 1923–40.

the total merchantable ore compared with an average of only 16 percent in 1923–32.

Most of the ore mined in the Southeastern district—the second-largest producing region—is obtained from underground operations. The output of merchantable ore per man-hour decreased slightly from 0.644 ton in 1939 to 0.639 ton in 1940. The largest and most consistent producing mines in the Southeastern district are in Jefferson County, Ala., where 4,623 men working 9,122,985 man-hours in 1940 produced 6,541,407 tons of merchantable ore, equivalent to an average output of 0.717 ton per man-hour. Virtually all ore produced in Jefferson County comes from underground mines. In comparing the man-hour cost of mining ore in this county, with that of underground mines in the Lake Superior district one should remember that, whereas the ore in the Lake Superior district is much richer in iron, the ore from the Jefferson County mines contains enough or almost enough lime to make it self-fluxing. Thus, the lower iron content is partly offset by the self-fluxing nature of the ore.

Figure 5 shows trends in production and employment at iron-ore mines in Jefferson County, Ala., 1923–40.

In the Northeastern district the average output of merchantable ore per man-hour decreased to 0.594 ton in 1940 from 0.654 ton in 1939. The drop in productivity was due in part to relatively larger increases in output from mines in New Jersey and New York, where virtually the entire output came from underground operations, resulting in a relatively higher expenditure of labor than in Pennsylvania, where output is predominantly from the open pit at Cornwall and productivity is high.

Trends in the technology, employment, and output per man in iron-ore mining over the past half century are covered in a recent report by Yaworski, Kiessling, and others.[10]

The accompanying table shows employment at iron mines and beneficiating plants, quantity and tenor of ore produced, and average output per man by districts and States in 1940. Corresponding statistics and supplementary data are given in Minerals Yearbook, 1934 to 1940, inclusive, and Minerals Yearbook, Review of 1940.

[10] Yaworski, N., Kiessling, O E., and others, Technology, Employment, and Output per Man in Iron Mining· W. P. A. Nat. Research Project, in cooperation with Bureau of Mines, U. S. Department of Interior, June 1940, 264 pp.

WORLD PRODUCTION

The following table shows the production of iron ore, by countries, from 1937 to 1941, insofar as statistics are available. Although complete returns for 1941 are not yet available it is evident that world production was much greater than in 1940.

World production of iron ore, 1937–41, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1937	1938	1939	1940	1941
North America:					
Canada	5,622	5,281	117,583	[2] 367,194	[2] 362,337

PIG IRON

PRODUCTION AND SHIPMENTS

Domestic production of pig iron, exclusive of ferro-alloys, increased 19 percent in 1941 over 1940 and established a new record. The output in 1941 comprised 54,981,489 net tons using coke and 103,957 tons using charcoal as fuel. Pennsylvania was the largest producer of pig iron in 1941, with 31 percent of the total; Ohio ranked second, with 23 percent. Of the pig iron manufactured in 1941, it is calculated that 1,381,893 tons valued at $27,404,941 were made from 2,388,610 tons of foreign ores, including ore from Africa, Australia, Brazil, Canada, Chile, Cuba, Palestine, and Spain, indicating an average yield of 57.85 percent from imported ore. Domestic ore (92,016,057 tons) and cinder, scale, and purchased scrap (8,175,648 tons) totaling 100,191,705 tons were reported as used in the manufacture of 53,703,553 tons of pig iron, indicating an average pig-iron yield of 53.60 percent from domestic materials. In addition, 1,588,000 tons of home scrap and 3,983,000 tons of flue dust were consumed in making pig iron in 1941.

Pig iron produced and shipped in the United States, 1940–41, by States

[1] Included under "Undistributed." [2] Includes statistics for States entered as "(1)."

Shipments of pig iron, exclusive of ferro-alloys, increased 18 percent in quantity and 32 percent in value in 1941 over 1940. The values given represent the approximate amounts received for the iron f. o. b. furnaces and do not include freight costs, selling commissions, and other items that are figured in some of the market prices for pig iron published by trade journals.

Pig iron shipped from blast furnaces in the United States, 1940–41, by grades

Grade	1940			1941		
	Net tons	Value		Net tons	Value	
		Total	Average		Total	Average
Charcoal	72, 461	$1, 755, 735	$24 23	144, 076	$3, 618, 686	$25. 12

VALUE AT BLAST FURNACES

The average value of all kinds of pig iron given in the accompanying table is based upon reports of producers to the Bureau of Mines. The figures represent the approximate values f. o. b. blast furnaces and do not include the values of ferro-alloys. The general average value for all grades of pig iron at the furnaces was $20.13 a net ton in 1941—$2.23 more than in 1940.

Average value per net ton of pig iron at blast furnaces in the United States, 1937–41, by States

State	1937	1938	1939	1940	1941
Alabama	$14.89	$13.10	$14.42	$14.30	$17.25
Illinois	18.85	18.15	18.02	18.05	20.79
Indiana	18.85	18.29	18.03	18.26	21.22

CONSUMPTION

Consumption of pig iron rose 22 percent in 1941 over 1940. Pig iron, a product of the blast furnace, is a semiraw material and, except for the small quantity used in direct castings, moves to other-type furnaces for further refining or mixture with other required ingredients. In general, it goes to steel-making or iron-making furnaces. By far the larger part is taken to steel-making furnaces (open-hearth, bessemer, and electric) for refining and processing into steel. In 1941, 86.4 percent of the pig iron was consumed in steel making. Direct castings took 2.8 percent of the 1941 total, and the remaining 10.8 percent was consumed in iron-making furnaces, of which the cupola is by far the most important. The consumption of pig iron, by types of furnace, for 1938 to 1941 is shown in the following table. Typically, the quantities of pig iron used in these furnaces are supplemented by the addition of ferrous scrap. The proportion of pig iron to scrap used in steel furnaces decreased in 1941 compared with 1940.

Consumption of pig iron in the United States, 1938–41, by type of furnace

Type of furnace or equipment	1938		1939		1940		1941	
	Net tons	Percent of total	Net tons	Percent of total	Net tons	Percent of total	Net tons	Percent of total

[1] Some pig iron used in making direct castings included in cupola. [2] Less than 0.05 percent.

The consumption of pig iron in this country is widespread, and plants using pig iron are situated in all 48 States, the District of Columbia, and Alaska. As expected from the uses of pig iron, consumption is concentrated largely in the iron- and steel-making centers of the North Central, Middle Atlantic, and Southeastern States. These areas in 1941 used about 98 percent of the pig iron, Pennsylvania (the leading consumer) taking about 31 percent of the total and Ohio (the second-largest consumer) nearly 21 percent. Of the chief consuming areas in 1941, the North Central district made the largest gain over 1940—26 percent compared with 19 percent in the Middle Atlantic district and 11 percent in the Southeastern district (including the Birmingham district of Alabama). The following table shows the distribution of pig-iron consumption by States from 1938 to 1941.

Consumption of pig iron in the United States, 1938–41, by States and districts

WORLD PRODUCTION

The accompanying table shows the production of pig iron by countries from 1937 to 1941 insofar as statistics are available. Although many of the leading world producers have been operating at a high rate for several years, the probable increase in world production during 1941 was due largely to the rise in United States production.

World production of pig iron (including ferro-alloys), 1937–41, by countries, in metric tons [1]

[1] Pig iron is produced in Chile, New Zealand, and the Philippine Islands in addition to countries listed, but production figures are not available.
[2] Year ended June 30.
[3] Estimate included in total.
[4] Data not available.
[5] Estimated production.
[6] Approximate production as published by The Iron Age, vol. 147, No. 1, January 2, 1941, p. 61.
[7] Approximate production as published by Steel, vol. 106, No. 1, January 1940, p. 269.
[8] Included in the German figure in 1940.
[9] Beginning with March 1935, production of the Saar is included with that of Germany.
[10] Does not include ferro-alloys.

FERRO-ALLOYS

Statistics concerning production and shipments of ferro-alloys during 1941 are omitted from this chapter to avoid the possibility of revealing information that might lend aid or comfort to the enemy.

FOREIGN TRADE

Imports of all alloys of the rarer metals are not recorded separately but are grouped as shown in the following table. Although spiegeleisen formed the bulk of the imports in 1940, there was a very noticeable decrease in withdrawals of this alloy and ferromanganese during the first 9 months of 1941, which totaled 7,268 net tons compared with 29,068 during the entire year 1940.

Imports of ferromanganese, January to September 1941, totaled 4,008 net tons containing 3,280 tons of manganese. Of this total, 3,993 net tons containing over 1 percent carbon came from Canada, and 15 tons of alloys containing less than 1 percent carbon were imported from Norway. All the ferrosilicon imported during the first 9 months of 1941 came from Canada.

From January to September 1941, inclusive, exports of ferro-alloys comprised 3,363 net tons of ferromanganese and spiegeleisen and 16,829 tons of other ferro-alloys, compared with 14,600 net tons of ferromanganese and spiegeleisen and 27,401 tons of other ferro-alloys during the full year 1940.

Ferro-alloys and ferro-alloy metals imported for consumption in the United States, 1940–41, by varieties

Variety of alloy	1940			1941 (Jan.-Sept.)		
	Gross weight (net tons)	Content (net tons)	Value	Gross weight (net tons)	Content (net) tons)	Value
Ferromanganese:						
Containing over 1 percent carbon	10,035	8,280	$1,121,133	3,993	3,267	$323,505

Ferro-alloys and ferro-alloy metals exported from the United States, 1940–41, by varieties

Variety of alloy	1940		1941 (Jan.–Sept.)	
	Net tons	Value	Net tons	Value
Ferromanganese and spiegeleisen	14,600	$1,366,087	3,363	$437,534
Other ferro-alloys [1]	27,401	7,064,823	16,829	4,252,369

[1] Includes ferrosilicon, ferrotungsten, ferrovanadium, and other ferro-alloys.

STEEL

PRODUCTION

The high operating rate of production established during the closing months of 1940 continued through all of 1941. The production rate was above 93 percent of capacity during each month and averaged 97 percent for the year, compared with 82 percent in 1940. Capacity for producing steel increased 4,418,000 net tons during the year to reach a new record total of 88,570,000 net tons. The following figures covering the output of steel were compiled by the American Iron and Steel Institute. The production of steel ingots and castings in 1941 established a new record and totaled 82,839,259 net tons.

Of the 1941 total, 89.8 percent was made in open-hearth furnaces, 6.7 percent in bessemer converters, 3.5 percent in electric furnaces, and only 2,313 tons in crucible furnaces. The bulk (73,232,959 tons) of the total open-hearth output in 1941 was made in basic furnaces. Of the total output of steel ingots and castings, 82,434,367 net tons were ingots in 1941 compared with 66,649,864 tons in 1940.

Pennsylvania and Ohio continued to lead all other States and produced about 53 percent of the total steel, 51 percent of the open-hearth steel, and 76 percent of the bessemer steel.

Open-hearth steel ingots and castings manufactured in the United States, 1937–41, by States, in net tons

	3,863,918	2,106,340	3,358,916	3,708,573	5,578,071

Steel electrically manufactured in the United States, 1937–41, in net tons

Includes only that portion of the steel for castings produced in foundries operated by companies manufacturing steel ingots]

Year	Ingots	Castings	Total	Year	Ingots	Castings	Total
1937	912,027	34,975	947,002	1940	1,608,032	91,974	1,700,006
1938	524,843	40,784	565,627	1941	2,758,611	110,645	2,869,256
1939	951,522	77,545	1,029,067				

The steel output for 1941 includes 8,174,961 net tons of alloy-steel ingots and castings, which represent 10 percent of the total. This figure includes steels in which the minimum of the range specified in any of the elements named exceeds the following percentages: Nickel, 0.40 percent; chromium, 0.30 percent; copper, 0.50 percent; manganese, 1.65 percent; silicon, 0.50 percent; molybdenum, 0.10 percent; vanadium, tungsten, cobalt, titanium, and zirconium, any percentage. The output of alloy steels in 1941 increased 65 percent and that of total steel 24 percent over 1940. Of the total alloy-steel output in 1941, 65 percent came from basic open hearths, 5 percent from acid open hearths, 30 percent from electric furnaces, 933 tons from crucible furnaces, and 3,890 tons from bessemer furnaces.

Production of alloy-steel ingots and castings, 1937–41, by processes, in net tons

[Includes only that portion of the steel for castings produced in foundries operated by companies manufacturing steel ingots]

Process	1937	1938	1939	1940	1941
Open-hearth, basic	2, 559, 200	1, 179, 031	2, 302, 273	3, 421, 961	5, 275, 247
Open-hearth, acid	164, 455	102, 089	156, 581	252, 965	433, 240
Bessemer	----------	13	3, 486	3, 990	3, 890
Crucible	270	5	231	255	933
Electric	672, 616	372, 372	749, 384	1, 286, 716	2, 461, 651
	3, 396, 541	1, 653, 510	3, 211, 955	4, 965, 887	8, 174, 961

From the foregoing tables it will be seen that most of the steel made in electric furnaces (86 percent in 1941) is alloy steel. Typically, steels with higher alloy content are made in electric furnaces and steels with lower alloy content by the open-hearth process.

FOREIGN TRADE AND PRODUCTION

Although data for only the first 9 months of 1941 are available for publication, it is evident that exports of iron and steel products continued at a high rate during the year. Exports of iron ore, pig iron, and ferro-alloys are covered in other sections of this report.

Imports for consumption of iron and steel products during the first 9 months of 1941 were very small—almost negligible compared with exports. The bulk of imports was in the form of rails and narrow strips not over 16 inches wide. Imports of these two commodities totaled 6,777 net tons during the first 9 months of 1941.

According to the Iron and Steel Institute, the steel capacity of Great Britain is approximately 20,600,000 tons and that of U. S. S. R. about 21,800,000 tons a year. Germany, Czechoslovakia, Poland, and Austria have produced as much as 24,700,000, 2,500,000, 1,700,000, and 700,000 net tons, respectively, a year. French maximum production was 10,700,000 net tons in 1929, a figure considerably in excess of actual production of succeeding years. Also, 1929 was the year during which Belgian production reached a maximum of 4,500,000 tons of steel. Japan's steel capacity is about 7,100,000 tons a year based upon estimates of 1940 output. Italian steel capacity is about 3,000,000 tons, the production peak reached in 1939. Luxemburg's steel industry reached its maximum output in 1929 when 3,000,000 tons were produced. In addition, the steel output of Hungary, Spain, and Sweden is about 800,000, 700,000, and 1,200,000 net tons, respectively. Data for 1941 are not available for Australia and India, but in each country the output of steel in 1940 represented a new peak, Australia producing 1,300,000 tons and India 1,200,000 tons.

Iron and steel exported from the United States, 1940–41

Article	1940		1941 (Jan.-Sept.)	
	Net tons	Value	Net tons	Value
Semimanufactures:

MANGANESE AND MANGANIFEROUS ORES

By NORWOOD B. MELCHER [1]

SUMMARY OUTLINE

GENERAL PERSPECTIVE

In 1941 history's greatest armament race was under way and overshadowed all other influences affecting the activity of the world's metal and mineral industries. To meet the demand for manganese created by an all-time record year of world steel production, all possible sources were stressed to the limit during 1941. The domestic production (shipments from domestic mines) of manganese ore containing 35 percent or more manganese in 1941 increased 95 percent over 1940; shipments were reported from 18 States in 1941, compared with 13 in 1940, and totaled 78,388 long tons. In addition, 457,287 long tons of ore containing 10 to 35 percent manganese and 820,290 tons of ore containing 5 to 10 percent manganese were shipped during the year.

A domestic manganese war program of sufficient scope to free American steel and alloy production from its present reliance on foreign sources, with accompanying dependence on ocean shipping and naval convoy where necessary, has been outlined by the Bureau of Mines.

The program is designed to provide enough manganese to produce 87 million tons of steel annually. It covers utilization of low-grade domestic manganese ores and was made possible through the development of several processes by the Bureau of Mines during years of study in laboratories and pilot plants.

The program provides for the establishment of 8 mills, 3 hydrometallurgical plants (including 1 electrolytic unit), and 1 matte smelting plant. The proposal is to establish these 12 plants in 10 locations in 8 States—Arizona, Arkansas, Minnesota, Montana, Nevada, New Mexico, South Dakota, and Utah. Construction periods for these plants would range from 9 to 12 months. Even with an increase of imports from Cuba and Mexico, a reduction of shipping from other foreign sources may result in a deficiency in manganese in 1943 unless additional domestic ores are processed. Supplies adequate for the present year and part of 1943 are now on hand.

It is estimated that a capital investment of less than $38,000,000 in mining operations and processing plants will be required to produce the quantity of manganese specified. A minimum of 526,000 tons of

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

metal annually is provided for in the program, with a maximum of approximately 560,000 tons. This includes 12,000 tons of electrolytic manganese, which is of special value in low-carbon steels and in certain types of stainless steels. Approximately 11,500,000 tons of domestic ores could be processed annually.

The program proposed by the Bureau of Mines is divided into two steps.

Six custom mills and one hydrometallurgical plant would be established first to handle the higher-grade ores. After careful consideration of the larger resources available and the methods of treatment suitable to each ore, the following locations were proposed: Custom concentrators at Deming, N. Mex.; Batesville, Ark.; Parker Dam, Ariz.; Philipsburg, Mont.; Delta, Utah; and Garfield, Utah; and a leaching plant and electrolytic plant at Las Vegas, Nev. These plants could produce a minimum of 213,620 tons of manganese (metal equivalent) annually and would require an investment of $14,100,000.

The second step in the program includes a concentrating plant at Artillery Peak, Ariz., one on the Cuyuna Range in Minnesota, and one at Chamberlain, S. Dak. These plants could produce a minimum of 312,175 tons of manganese (metal equivalent) annually and would require an investment of $24,000,000.

Ore from 50 different deposits could be used in the program, including properties in the Batesville-Cushman district in Arkansas; the Aquila, Parker Dam, and Wickenburg areas in Arizona; the Paymaster district in California; the Granite County, West Butte, and Wickes areas in Montana; the Drum Mountain, Simpson Mountains, Kanab, Marysvale, and Tintic districts in Utah; the Caliente, Ely, Pioche, Battle Mountain, and Valmy areas in Nevada; the Three Kids, Annex, and Las Vegas-Wash areas in Nevada; the Cleveland area in Idaho; the Cuyuna Range area in Minnesota; and the South Dakota area near Chamberlain.

The program includes the advance purchase and stock-piling of ores during the period of construction of the mills and hydrometallurgical plants so that full operation could be attained rapidly.

Figure 1 shows imports and domestic production of manganese ore over a 42-year period.

Salient statistics of the manganese industry in the United States, 1925–29 (average) and 1937–41, in long tons

	1925–29 (average)	1937	1938	1939	1940	1941
Manganese ore:						
Total shipments containing 35 percent or more Mn	59,312	40,241	25,321	29,307	40,123	78,388
Shipments of metallurgical ore	[1] 41,892	26,419	16,989	18,580	27,158	65,939
Shipments of battery ore	17,420	6,447	4,959	7,767	9,271	10,178
Imports for consumption	600,000	911,919	483,586	627,129	1,282,079	1,530,876
Ferro-alloys:						
Production of ferromanganese	306,360	376,443	242,994	270,111	459,538	518,486
Imports of ferromanganese [2] [3]	[4] 50,590	23,888	21,118	33,414	8,573	5,085
Production of spiegeleisen	95,463	([5])	11,311	91,491	101,892	158,853
Imports of spiegeleisen [2]	7,298	16,841	17,248	38,264	15,585	4,233
Exports of spiegeleisen and ferromanganese	3,769	1,725	247	2,923	13,036	4,603

[1] Includes small quantity of miscellaneous ore.
[2] Imports for consumption.
[3] Manganese content.
[4] Includes small quantity of other manganese alloys.
[5] Bureau of Mines not at liberty to publish figures.

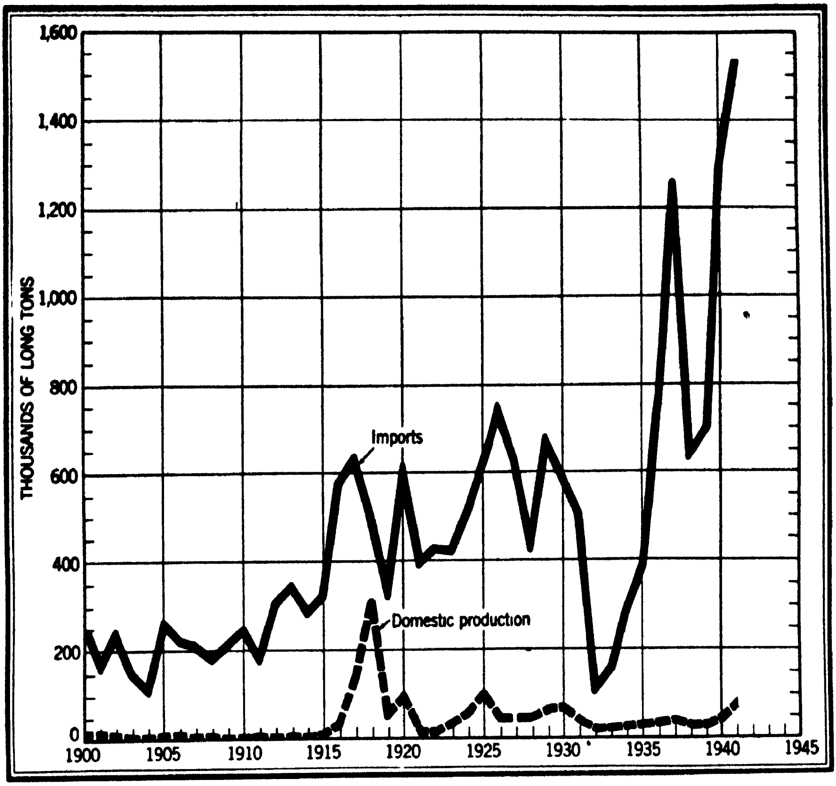

FIGURE 1.—Imports and domestic production (mine shipments) of manganese ore, 1900–1941. Statistics on imports shown in the graph represent "general imports" for the period 1900–1933; beginning with 1934, data classified as "general imports" were not available, and the figures plotted for 1934–41 represent imports for consumption adjusted for changes in stocks in bonded warehouses and are closely comparable with the record for earlier years.

Government Purchases.—The following schedule regarding Government purchases of manganese ore, effective May 4, 1942, was published by the Metals Reserve Co. The terms are subject to change without notice and do not apply to ores originating outside the limits of continental United States.

1. *Quantity:* One thousand (1,000) to ten thousand (10,000) long tons per contract. Contracts in excess of ten thousand tons may be obtained as a result of individual negotiations, provided reliable and complete engineering data submitted by the applicant warrant a contract for a larger quantity.

2. *Term of Contract:* Deliveries must be completed within eighteen (18) months of the date of contract. If delivery of twenty percent (20%) of the tonnage contracted for has not been made within 6 months of date of contract, Buyer may cancel contract forthwith.

3. *Quality:* Purchases of domestic manganese ores are of three grades with the following specifications:

(*a*) *Black oxide ores:* The schedule of prices and the terms and conditions herein refer to black oxide ores of manganese.

(*b*) *Concentrates:* Manganese concentrates to be acceptable under this schedule must be nodulized or sintered.

(*c*) *Carbonate ores:* Manganese carbonate ores will be accepted under this schedule only if calcined.

		"High-Grade"	"Low-Grade A"	"Low-Grade B"
Manganese	Minimum	48.0 %	44.0 %	40.0%.*
Alumina	Maximum	6.0 %	10.0 %	No maximum.
Iron	Maximum	7.0 %	10.0 %	No maximum.
Phosphorus	Maximum	.18%	.30%	0.50%.
Silica	Maximum	10 0 %	15.0 %	No maximum.
Zinc	Maximum	1.0 %	1.0 %	1.0%.

* Under "Low-Grade B," manganese ore will be accepted to 35.0% minimum under penalties hereinafter prescribed.

Size of ore: None in excess of 12 inches and not more than 25% to pass a 20-mesh screen.

Buyer may reject any shipment which does not conform to the applicable requirements and specifications as set forth above.

4. *Price:* Effective May 4, 1942, contracts will be considered on the following schedule for domestic ores, within continental United States (excluding Alaska); all prices per long ton (2,240 pounds) of dry weight, f. o. b. cars at stock pile designated by Buyer.

"High-Grade"—Base price, $48.00 per long dry ton for ore containing 48.0% manganese with an increase of one dollar ($1.00) per ton for each unit (22.4 pounds) in excess of 48.0%; fractions prorated. "High-Grade" ore containing not less than 48.0% manganese but otherwise falling below specifications but within the limits hereinafter set forth will be accepted subject to the following penalties:

Iron—Up to 10.0% maximum with a penalty of 1¢ per unit for each percent in excess of 7.0%; fractions prorated;

Silica—Up to 15.0% maximum with a penalty of 1¢ per unit for each percent in excess of 10.0%; fractions prorated;

Alumina—Up to 10.0% maximum with a penalty of 1¢ per unit for each percent in excess of 6.0%; fractions prorated;

Phosphorus—Up to 0.30% maximum with a penalty of 1¢ per unit for each 0.03% in excess of 0.18%; fractions prorated.

"Low-Grade A"—Base price, $35.20 per long dry ton for ore containing 44.0% manganese with an increase of eighty cents ($0.80) per ton for each unit (22.4 pounds) in excess of 44.0%; fractions prorated.

"Low-Grade B"—Base price $26.00 per long dry ton for ore containing 40.0% manganese with an increase of sixty-five cents ($0.65) per ton for each unit (22.4 pounds) in excess of 40.0%; fractions prorated. Ore containing a minimum of 35.0% manganese will be accepted under this schedule with a penalty of $1.30 per ton for each unit (22.4 pounds) less than 40.0%; fractions prorated.

In addition to the above prices, an allowance will be made for each long ton shipped equal to the freight tariff per long ton from Seller's nearest convenient rail station to Buyer's stock pile.

The cost of sampling and analysis by the Buyer, weighing, and unloading onto stock pile will be for the account of Buyer.

Under the contract, each lot will be priced under the grade within which the specifications fall. Thus a lot carrying 45% manganese but also 0.50% phosphorus would be priced as "Low-Grade B."

5. *Shipment and Delivery:* Seller will give such advice regarding shipment and arrival as Buyer may require at least ten days prior to shipment of the ore from point of loading onto railroad cars; otherwise, any demurrage at the stock pile will be for Seller's account.

Shipment will be made in flat-bottom gondolas, if available, in lots of not less than one carload, to the stock pile designated by Buyer. Seller will prepay the freight to such stock pile, where the ore will be weighed in cars, light and loaded, on track scales, and sampled for moisture. The lot will be sampled as unloaded and upon receipt of analysis, Buyer will advise Seller as to whether the ore is acceptable and under what classification.

If the lot is ascertained to be unacceptable under the above specifications, Seller will not be entitled to any allowance for prepaid freight and will be held responsible for the removal of this shipment of ore from the stock pile location. Upon failure so to remove the ore within fifteen days of due notice, Buyer may, at its absolute discretion, remove such ore and the cost of such removal shall be for Seller's account; or Buyer may, at its option, otherwise dispose of such ore without

any liability therefor. In the event that Seller fails to repay Buyer for the cost of removal within fifteen days after notice, Buyer may cancel the contract forthwith.

6. *Payment:* As soon as moisture and analysis determinations are received, Buyer will promptly pay Seller in accordance with the weight certificate and the above schedule.

7. *Weights:* The weight paid for will be net railroad track scale weights (weight of loaded car less weight of empty car), less moisture as determined by standard practice.

8. *Sampling and Analysis:* Each lot will be sampled at the time of unloading onto stock pile by a sampler designated by Buyer, three samples being taken, one for each Seller, Buyer, and Umpire, and analysis made for manganese and other guaranteed elements. Usual provisions will be made for splitting limits and settlement by average of Seller's and Buyer's analyses, or by trade practice if samples are sent to Umpire. Moisture samples will be taken in accordance with standard practice. Seller may have representative at sampling at his own expense.

9. *Application for Contract:* Forms may be obtained upon request from the Metals Reserve Co., 811 Vermont Avenue, NW., Washington, D. C. All the information called for on the application form must be supplied before consideration can be given to granting a contract.

Safety.—With increased activity of manganese ore operations, attention is called to the toxic effect of breathing dust containing appreciable quantities of manganese. In 1941 a study was made by Flinn and others[2] of this hazard. An abstract of this work follows:

The occurrence of chronic manganese poisoning among the 34 employees of a manganese ore-crushing mill was found to vary with the atmospheric manganese concentration and with the length of employment. Eleven cases were found. None of the 9 men exposed to less than 30 mg. of manganese per cubic meter was found to have the disease although only 2 of these 9 men had been employed more than 3 years; on the other hand, 5 of the 6 men exposed for more than 3 years to atmospheric manganese concentrations exceeding 90 mg. per cubic meter were found to have the disease. Tests made in a modern mill showed that the workers' exposure could be reduced to at most 6 mg. per cubic meter by the use of enclosed machinery, mechanical conveyors, and exhaust ventilation.

The disease is characterized by muscular incoordination which becomes evident first in the form of difficulty in walking. Later, many parts of the body may be affected and disability results. Most of the usual laboratory tests applied to blood, urine, and cerebrospinal fluid gave normal results. However, manganese-affected workers had low leucocyte counts, particularly in neutrophilic cells, and in Lange's test the middle range of dilutions of cerebrospinal fluid gave slightly positive reactions.

Recommendations for medical and engineering control are incorporated.

DOMESTIC PRODUCTION[3]

The following table shows the various types of manganiferous materials shipped by domestic producers during 1937 to 1941.

Manganiferous raw materials shipped by producers in the United States, 1937–41, in long tons

Year	Metallurgical ore (ferrous metallurgy only)				Battery ore	Miscellaneous manganese ore
	Manganese ore (35 percent or more Mn)	Ferruginous manganese ore (10 to 35 percent Mn)	Manganiferous iron ore (5 to 10 percent Mn)	Manganiferous zinc residuum		
1937	26,419	151,955	1,189,017	115,998	6,447	7,375
1938	16,989	33,620	275,240	39,079	4,959	3,373
1939	18,580	239,544	469,703	129,238	7,767	2,960
1940	27,158	320,006	816,541	154,455	9,271	3,694
1941	65,939	457,287	820,290	251,829	10,178	2,271

[2] Flinn, Robert H., Neal, Paul A., Reinhart, Warren H., Dallavalle, J. M., Fulton, William B., M. D., and Dooley, Allan E., Chronic Manganese Poisoning in an Ore-Crushing Mill: Public Health Service, Public Health Bull. 247, 1941, p. vii.

[3] Throughout chapter, unless otherwise indicated, percentages expressing manganese content of ores refer to ores in natural (undried) state.

Shipments of the various grades of manganese ore during the last 5 years are given, by States, in the following tables. In addition, battery-grade ores were produced in Arizona, California, and Montana; manganiferous zinc residuum was produced from New Jersey zinc ores; and miscellaneous manganese ores came from Alabama, California, Georgia, Montana, Tennessee, Virginia, and West Virginia.

Metallurgical manganese ore shipped from mines in the United States, 1937–41, by States, in long tons

[1] Included under "Undistributed."
[2] 1 producer in Georgia, 2 in Tennessee, and 5 in Virginia shipped both metallurgical and miscellaneous ore.
[3] Value for Georgia included with Minnesota.
[4] 1 producer in Montana shipped metallurgical, battery-grade, and miscellaneous ore.

Alabama.—Production in Alabama was small during 1941, and all was miscellaneous-grade ore. Three producers, one each in Cherokee, Etowah, and Jefferson Counties, supplied the total of 165 long tons.

Arizona.—Norman W. McGregor shipped a small quantity of battery-grade ore averaging 41.6 percent manganese from the Black Warrior mine in Mohave County. The largest shipper from Arizona during 1941 was Apache Mines, Inc., with operations at the Apache mines in Gila County and the Casa Grande mine in Pinal County. Shipments averaged 44.4 percent manganese. In addition, small quantities were shipped by 10 other producers in Cochise, Coconino, Gila, Pinal, Yavapai, and Santa Cruz Counties.

Arkansas.—Most of the manganese ore from Arkansas in 1941 came from the Batesville-Cushman district of Independence County and was supplied by the Walter H. Denison Manganese & Contracting Co., Inc., and the Arkansas Manganese Co. The North American Manganese Corporation made an initial shipment of metallurgical ore from Pike County in western Arkansas; this ore averaged 48.69 percent manganese (dry).

A study of the beneficiation of manganese wad ores from Batesville, Ark., has been made by Shelton and coworkers.[4]

California.—A great increase in manganese-mining activity was apparent in California during 1941. Manganese ore was shipped by 10 producers in 7 counties compared with only 2 producers in 1940. Shipments during 1941 were reported from Imperial, Plumas, San Bernardino, San Joaquin, Santa Clara, Stanislaus, and Trinity Counties. William Clark Crittendon shipped 976 tons of battery-grade ore from the Black Wonder-Jones mines in Stanislaus County. In addition, 414 tons of ferruginous manganese ore were shipped from Santa Clara and Trinity Counties during the year.

Colorado.—J. D. Thomas at Iola and Strategic Minerals, Inc., in San Miguel County supplied the State total of 170 tons of metallurgical-grade ore during 1941.

Georgia.—All ore containing 35 percent or more manganese and nearly all other manganese-bearing ores shipped from Georgia in 1941 came from Bartow County. Small quantities of ferruginous manganese ore were shipped from Fannin and Polk Counties. Bearden & Mosteller shipped 1,064 tons of manganiferous ore from the Cartersville district. Miscellaneous ores were shipped by Bearden & Mosteller and the Manganese Mining Co., both of Cartersville.

A study of the concentration of these ores was made by Johnston and coworkers.[5]

Idaho.—The Metalloy Corporation, Cleveland, Idaho, made the only shipment of manganese ore made from Idaho in 1941—that from the Hot Spot mine. Three producers shipped a total of 348 tons of ferruginous manganese ore during the year.

Massachusetts.—Anson G. Betts shipped ferruginous manganese ore averaging 20 percent manganese from the Taconic mine in Hampshire County.

Minnesota.—Ferruginous manganese ore averaging 12.62 percent manganese was shipped from the Alstead-Hillcrest, Louise, and Merritt mines. Manganiferous iron ore averaging 6.90 percent manganese

[4] Shelton, S. M., Fine, M. M., and Bardill, J. D., Beneficiation of Manganese Wad Ores from the Chinn Property, Batesville, Ark. Bureau of Mines Rept. of Investigations 3614, 1942, pp. 1–18.

[5] Johnston, T. L., Fine, M. M., and Shelton, S. M., Concentration of Manganese-Bearing Ore from the Dobbins Mine, Cartersville, Ga.: Bureau of Mines Rept. of Investigations 3608, 1942, pp. 1–32.

came from the Louise, Merritt, Sagamore, and Mahnomen mines. All shipments during 1941 came from the Cuyuna Range in Crow Wing County.

A study of the production of ferromanganese-grade concentrates from these ores has been made by Shelton and Fine.[6]

Missouri.—Ernest Pearce shipped a small quantity of metallurgical-grade ore from Washington County during 1941.

Montana.—Sixty-two percent of the total United States production of manganese ore during 1941 came from Montana. The bulk of the battery-grade ore came from the Philipsburg district and averaged about 70 percent MnO_2; however, several cars of battery-grade ore were shipped from the Emma mine near Butte. A total of 4,454 tons of ferruginous manganese ore was shipped from the Trout mine in the Philipsburg district. The Anaconda Copper Mining Co. at Butte shipped 59 percent of the United States total of metallurgical manganese ore in 1941 and was the most important development of the year from a standpoint of tonnage produced; shipments of calcined nodules from Anaconda were begun in June in fulfillment of its contract with the Metals Reserve Co. The concentration process is described by Huttl [7] and consists of selective flotation, which recovers manganese, lead, zinc, and silver. The rhodochrosite nodules are calcined before shipment.

Deposits of the Philipsburg district are described in detail by Goddard.[8]

Nevada.—H. E. Chatwin and R. H. Richards shipped 2,622 tons of metallurgical ore averaging 37.6 percent manganese and 7,958 tons of ferruginous manganese ore from the Black Diablo mine in Humboldt County and the Black Rock mine in Lander County.

New Mexico.—No shipments of manganese ore were made from New Mexico in 1941. The Luna Manganese Co. of Deming produced about 250 tons of concentrates, which were shipped early in 1942. The Luck Mining & Construction Co. shipped the bulk of the ferruginous manganese ore from the Boston Hill mine in Grant County.

Lasky [9] has described manganese deposits in the Little Florida Mountains, Luna County, and De Vaney and coworkers [10] have studied the concentration of ores from that district.

North Carolina.—The National Metals Corporation shipped 31 tons of metallurgical ore from the Bald Knob mine in Alleghany County, and ferruginous manganese ore was shipped from McDowell County.

Oklahoma.—Robert Galbreath shipped metallurgical ore and ferruginous manganese ore from Coal and Johnston Counties.

Oregon.—Seventy-six tons of manganese ore averaging 46.67 percent manganese were shipped from the McAdams property in Coos and Curry Counties during 1941.

South Dakota.—No production of manganese-bearing ore in 1941 for commercial purposes was reported from South Dakota. How-

ever, the Bureau of Mines has done extensive work on the concentration of nodules and recovery of manganese from the manganiferous shales near Chamberlain in south-central South Dakota. This is one of the most extensive of our possible sources of manganese. Gries and Rothrock [11] estimate the manganese content of the deposit to be as high as 850,000,000 tons and state that it is safe to assume that at least 50,000,000 tons of nodules can be recovered from the areas free of overburden and suitable for open-pit mining.

De Vaney and coworkers [12] have studied concentration of manganese nodules from Chamberlain, and Wood and coworkers [13] recovery of manganese from nodules.

Tennessee.—Manganese-bearing ores were shipped from Johnson, Unicoi, and Washington Counties during 1941. The Embree Iron Co., Unicoi County, and the Interstate Manganese Co., Johnson County, shipped the bulk of the total ore—from the Embree and Greer mines.

Reichert [14] has recently given a detailed description of the manganese resources of East Tennessee, and Johnston and coworkers [15] have studied the concentration of Tennessee ores.

Utah.—F. W. De Friess made Utah's only shipment of manganese ore, from a mine near Green River in Grand County. Ferruginous manganese ore was shipped from six properties in Grand, Juab, Kane, and Sevier Counties.

Zimmerley and coworkers[16] have studied concentration of Drum Mountain ores.

Virginia.—Twenty-one shippers of metallurgical-grade ore and 11 shippers of miscellaneous ore (5 shipping both grades) supplied 4,449 tons of metallurgical and 989 tons of miscellaneous ore during 1941. Shipments of manganese ore were made from Appomattox, Augusta, Bath, Bland, Campbell, Craig, Frederick, Giles, Grayson, Page, and Smyth Counties. In addition, 3,906 tons of ferruginous manganese ore were shipped from Augusta, Bland, and Giles Counties during the year.

Washington.—The Sunshine Mining Co. shipped 1,418 tons of manganese ore containing 49.34 percent manganese from the Crescent mine in Clallam County during 1941. A very small shipment of ferruginous manganese ore was shipped from the Stevens Creek mine in Grays Harbor County.

West Virginia.—The Appalachian Ores Co. shipped 2,195 tons of metallurgical ore and 400 tons of ferruginous manganese ore from the Sweet Springs mine in Monroe County. Five tons of miscellaneous ore were shipped from a mine in Pendleton County.

IMPORTS OF MANGANESE ORE

Imports for consumption of manganese ore containing 35 percent or more manganese increased 19 percent in 1941 over 1940 and comprised 1,498,667 long tons of metallurgical ore containing 719,096 tons of manganese valued at $24,165,221 and 32,209 tons of battery-grade ore containing 17,472 tons of manganese valued at $920,610. All supplying countries except Gold Coast and U. S. S. R. made larger shipments than in 1940; the most noticeable increases came from Brazil, Cuba, British India, and Union of South Africa, and these four countries supplied 80 percent of the total in 1941. Of the battery-grade ore, 25,347 tons came from Gold Coast, 4,574 tons from Union of South Africa, 2,090 tons from Netherlands Indies, 139 tons from Mexico, 57 tons from British India, and 2 tons from Canada.

General imports (containing 35 percent or more manganese), which represent the movement of ore into this country, were 9 percent less than imports for consumption and totaled 1,394,762 long tons containing 654,710 tons of manganese. Of this ore 387,348 tons came from Brazil, 322,241 tons from British India, 261,374 tons from Union of South Africa, and 243,405 from Cuba; and these four countries supplied 87 percent of the total in 1941. Included in the total ore are receipts of battery-grade ore amounting to 28,995 tons (containing 15,840 tons of manganese), of which Gold Coast supplied 22,804 tons, or 79 percent.

No imports for consumption of ferruginous manganese ore (containing 10 to 35 percent manganese) were recorded during 1941. Imports of manganiferous ore (5 to 10 percent manganese) are estimated at 2,022 tons.

Manganese ore (35 percent or more Mn) imported into the United States, 1940–41, by countries

Country	General imports [1] (long tons)				Imports for consumption [2]

[1] Comprises ore received in the United States during year, part went into consumption and remainder entered bonded warehouses

[2] Comprises receipts during year for consumption and ore withdrawn from bonded warehouses during year (irrespective of time of importation).

CONSUMPTION AND STOCKS OF MANGANESE RAW MATERIALS

The following table shows actual consumption of manganese ore (containing 35 percent or more manganese (natural)) and alloys during 1941 and stocks at the end of the year. As this table is the result of the first study of this type conducted by the Bureau of Mines, there are no comparable statistics for earlier years.

Manganese ore and manganese alloys consumed and in stock[1] in the United States in 1941, gross weight in long tons

	Consumed	In stock Dec. 31, 1941 [1]

Ferromanganese	520,054	184,793	29,101
Spiegeleisen	144,120	73,922	
Silicomanganese	41,294	7,646	1,304

[1] Exclusive of Government stocks.

The following table shows ores available for consumption in the United States during 1941. The table does not consider consumers or Government stocks at beginning and end of the year.

Indicated consumption of manganiferous raw materials in the United States in 1941

	Ore containing 35 percent or more Mn		Ore and residuum containing 10 to 35 percent Mn		Ore containing 5 to 10 percent Mn	
	Long tons	Mn content (percent)	Long tons	Mn content (percent)	Long tons	Mn content (percent)
Domestic shipments	78,388	50.6	709,116	15.4	820,290	6.9
Imports for consumption	1,530,876	48.1	-	-	[1] 2,022	7.2
Total available for consumption	1,609,264	48.2	709,116	15.4	822,312	6.9

[1] Estimated.

In addition to the foregoing, 1,592,700 long tons of domestic ore containing 2 to 5 percent manganese were shipped from mines in 1941, and presumably used in the manufacture of pig iron, compared with 737,400 tons in 1940 and 652,900 tons in 1939. Figures for imports of ore of this class are not available.

METALLURGICAL INDUSTRY

Although manganese is used in both the ferrous and nonferrous metallurgical industries, the bulk is consumed in the manufacture of iron and steel. Most of the ore entering the industry is used in the manufacture of ferromanganese and spiegeleisen, the forms in which manganese ordinarily is added to steel.

Ferromanganese and spiegeleisen imported into and made from domestic and imported ores in the United States, 1940–41, in long tons

	1940		1941	
	Alloy	Manganese	Alloy	Manganese

[2] Less than 0.01 percent.

Ferromanganese.—The domestic output of ferromanganese in 1941, which increased 13 percent over 1940, was produced at the following plants:

Bethlehem Steel Co., Johnstown, Pa.
Carnegie-Illinois Steel Corporation, Etna, Duquesne, and Clairton, Pa.
Electro Metallurgical Co., Alloy, W. Va., and Niagara Falls, N. Y.
E. J. Lavino & Co. Reusens, Va., and Sheridan, Pa.
Sloss-Sheffield Steel & Iron Co., North Birmingham, Ala.
Tennessee Products Corporation, Rockdale and Rockwood, Tenn.
Keokuk Electro-Metals Co., Keokuk, Iowa.

In addition to the foregoing plants, shipments were made by the Colorado Fuel & Iron Corporation, Pueblo, Colo., and the Jones & Laughlin Steel Corporation, Aliquippa, Pa.

The larger part of the ferromanganese produced in this country is made from foreign ores, as shown in the following table:

Ferromanganese produced in the United States and metalliferous materials consumed in its manufacture, 1937–41

Year	Ferromanganese produced			Materials consumed (long tons)				Manganese ore used per ton of ferromanganese made (long tons)
	Long tons	Manganese contained		Manganese ore (35 percent or more Mn, natural)		Iron and manganiferous iron ores	Cinder, scale, and purchased scrap	
		Percent	Long tons	Foreign	Domestic			
1937	376,443	79.54	299,425	698,052	9,444	17,511	6,017	1.879
1938	242,994	78.65	191,104	416,738	22,548	9,696	8,462	1.808
1939	270,111	79.24	214,040	502,986		8,324	6,250	1.862

	698,052	416,738	502,986	871,725	1,001,953

[1] Tonnage entered under "Undistributed" comprises ore from India and U. S. S. R., separation as to source not reported by consumer.

Shipments of ferromanganese in 1941 increased 23 percent over 1940. The record of shipments during the past 5 years is as follows:

Ferromanganese shipped from furnaces in the United States, 1937–41

Year	Long tons	Value	Year	Long tons	Value
1937	359,842	$30,696,748	1940	449,367	$42,755,485
1938	223,720	19,144,884	1941	553,031	69,378,004
1939	296,631	24,137,211			

Imports for consumption and exports decreased 39 and 65 percent, respectively, in 1941 from 1940. Ferromanganese imported for consumption in 1941 comprised 13 tons containing not over 1 percent carbon and 6,265 tons containing not less than 4 percent carbon.

Ferromanganese imported into and exported from the United States, 1937–41

Year	Imports for consumption			Exports [1]	
	Gross weight (long tons)	Mn content (long tons)	Value	Gross weight (long tons)	Value
1937	29,559	23,888	$2,163,616	1,725	$72,502
1938	26,258	21,118	1,770,948	247	18,799
1939	41,227	33,414	2,935,214	2,923	247,798
1940	10,369	8,573	1,321,369	13,036	1,366,087
1941	6,278	5,085	557,150	4,603	771,575

[1] Includes spiegeleisen; not separately classified prior to July 1, 1941.

Imports of ferromanganese in 1940 and 1941, by countries, are shown in the following table.

Ferromanganese imported for consumption in the United States, 1940–41, by countries

Country	1940		1941	
	Mn content (long tons)	Value	Mn content (long tons)	Value
Canada			1,073	$136,029
Japan	35	$2,349		
Norway	8,538	1,319,020	11	1,597
United Kingdom			4,001	419,524
	8,573	1,321,369	5,085	557,150

Customs districts through which imported ferromanganese entered in 1940 and 1941 are as follows:

Manganese content of ferromanganese imported for consumption in the United States, 1940–41, by customs districts, in long tons

Customs district	1940	1941	Customs district	1940	1941
Buffalo	992	969	New York	529	
Los Angeles	79		Oregon	38	
Maryland	6,731	4,001	Vermont		20
Michigan		95	Washington (State)	47	
New Orleans	157			8,573	5,085

The quoted price of ferromanganese was unchanged throughout 1941, as shown in the following table.

Prices per long ton of ferromanganese in the United States, 1939-41 [1]

[80 percent—delivered at Pittsburgh]

Month	1939	1940	1941	Month	1939	1940	1941
January	$91.58	$105.33	$125.33	July	$85.33	$125.33	$125.33
February	85.33	105.33	125.33	August	85.33	125.33	125.33
March	85.33	105.33	125.33	September	95.33	125.33	125.33
April	85.33	105.33	125.33	October	105.33	125.33	125.33
May	85.33	105.33	125.33	November	105.33	125.33	125.33
June	85.33	105.33	125.33	December	105.33	125.33	125.33

[1] Steel, vol. 110, January 5, 1942.

Spiegeleisen.—Domestic shipments of spiegeleisen in 1941 increased 52 percent over 1940 and 91 percent over 1939.

Spiegeleisen produced and shipped in the United States, 1937-41

Year	Produced (long tons)	Shipped from furnaces		Year	Produced (long tons)	Shipped from furnaces	
		Long tons	Value			Long tons	Value
1937	(1)	134,983	$3,969,822	1940	101,892	106,707	$3,487,565
1938	11,311	24,939	728,830	1941	158,853	161,765	5,793,481
1939	91,491	84,739	2,484,042				

[1] Bureau of Mines not at liberty to publish figures.

Spiegeleisen was manufactured at the following plants during 1941:

Carnegie-Illinois Steel Corporation, Duquesne and Clairton, Pa., and Gary, Ind.
New Jersey Zinc Co., Palmerton, Pa.
Sloss-Sheffield Steel & Iron Co., North Birmingham, Ala.

Most of the spiegeleisen produced in the United States is made from domestic raw materials. However, 1,683 tons of Brazilian ore containing 42.14 percent manganese and 143 tons of Cuban ore containing 50.73 percent manganese were consumed in the production of spiegeleisen during 1941. Imports of spiegeleisen for consumption in 1941 decreased 73 percent from 1940. The total supply came from Canada.

Spiegeleisen imported for consumption in the United States, 1937-41

Year	Long tons	Value	Year	Long tons	Value
1937	16,841	$589,766	1940	15,585	$638,732
1938	17,248	625,480	1941	4,233	215,108
1939	38,264	1,329,814			

The prices of spiegeleisen (20 percent) at producers' furnaces, as quoted by Steel, remained constant at $36.00 a ton throughout 1941.

Manganiferous pig iron.—Precise data on the consumption of manganiferous ores in the production of manganiferous pig iron are not available. However, 820,290 long tons of domestic ore containing 5 to 10 percent manganese and 1,592,700 tons containing 2 to 5 percent manganese were shipped during 1941. A small amount of foreign manganiferous iron ore (2,022 tons) and 7,422 tons of foreign ferruginous manganese ore were also consumed in the manufacture of pig iron.

Foreign ferruginous manganese ore and manganiferous iron ore consumed in the United States, 1939–41, in long tons

Source of ore	Ferruginous manganese ore			Manganiferous iron ore		
	1939	1940	1941	1939	1940	1941
Africa	1,184	184				
Asia. Palestine	1,133	36,069				
Australia				54,941	11,905	2,022
Brazil		746	7,422	6,831		
Sweden				985	523	
Undistributed	582					
	2,899	36,999	7,422	62,757	12,428	2,022

BATTERY INDUSTRY

Shipments of manganese ore from Arizona, California, and Montana by domestic producers to battery makers in 1941 totaled 10,178 long tons. Imports of battery-grade ore for consumption were 32,209 long tons containing 17,472 tons of manganese. Manganese ore for battery use should have a high content of available oxygen with minimum iron and be comparatively free from such metals as arsenic, copper, nickel, or cobalt, which are electronegative to zinc.

MISCELLANEOUS INDUSTRIES

Small quantities of manganese ores are used in the glass, paint and varnish, pigments and dyes, and other miscellaneous industries. No accurate statistics are available to show the amount of manganese ore used for these purposes in this country, but it is known to be very small, probably less than 5,000 tons a year.

PRICES

Prices of manganese ore (except battery ore) are upon a unit basis, the unit being 1 percent of a long ton or 22.4 pounds of contained manganese. Prices of battery-grade ore are quoted upon a per-ton basis, with a minimum requirement of manganese dioxide.

A complete price schedule for domestic ore is given in the early pages of this chapter under "Government Purchases"; effective May 4, 1942, the price rose to $1.00 per unit for 48-percent-grade ore. The average value reported for ore containing 35 percent or more manganese during 1941 was about 63 cents per unit. Quotations on imported ore in the following table are from the Engineering and Mining Journal. A duty of one-half cent per pound of contained manganese is imposed on all imported manganese ore except that from Cuba and the Philippine Islands, which enters duty free.

Domestic prices of metallurgical manganese ore in 1941, in cents per long-ton unit

[C. i. f. North Atlantic ports, cargo lots, exclusive of duty]

	Beginning of year	End of year		Beginning of year	End of year
Brazilian, 46–48 percent Mn	$0.50	$0.63	Cuban (not dutiable)		
Chilean, 47–48 percent Mn	.52	.65	50–52 percent Mn	$0.65	$0.78
South African, 50–52 percent Mn	.55	.68	45–47 percent Mn	.55	.73

According to the Engineering and Mining Journal, prices for chemical (battery-grade) ores per long ton in carlots at the end of 1941 were as follows: Domestic, containing 70 to 72 percent MnO_2, \$45 to \$50; Brazilian or Cuban, 80 percent MnO_2, \$55; Javan or Caucasian, 85 percent MnO_2, nominal.

WORLD PRODUCTION

Manganese ore produced in principal countries of the world, 1937–41, in metric tons [1]

[Compiled by B. B. Waldbauer]

[1] In addition to countries listed, Belgium produces manganese ore, but data of output are not available. Czechoslovakia reports a production of manganese ore, but as it has been ascertained that the product so reported averages less than 30 percent Mn and therefore would be considered ferruginous manganese ore under the classification used in this report, the output has not been included in the table.
[2] Data not available.
[3] Shipments by rail and river.
[4] Exports.
[5] Salable.
[6] January to October, inclusive.
[7] Estimated.
[8] Exports January to June, inclusive.
[9] January to June, inclusive.

Brazil.—Production of manganese ore in Brazil increased greatly in 1941 over 1940. Exports totaled 437,402 metric tons compared with 270,000 tons in 1940. Nearly all the exports came to the United States, which imported 393,565 metric tons in 1941. Brazil was the largest supplier of manganese ore imported into the United States during the year. Stocks on hand in Rio de Janeiro on December 31, 1941, were 32,010 metric tons compared with 68,212 tons at the end of 1940. During the first quarter of 1942, all exports from Brazil came to United States.

Chile.—Exports from Chile totaled 21,396 metric tons in 1941 compared with 19,518 tons in 1940; 17,409 metric tons reached the United States during 1941.

Cuba.—A concentrating plant at Cristo near Santiago, Cuba, was expanded 30 percent to make possible a production of 130,000 tons of high-grade ore during 1941. A considerable quantity of ore was purchased from small producers to make this production possible. Total Cuban production in 1941 was 191,937 metric tons.

Mexico.—Production of manganese ore in Mexico was 979 metric tons in 1941 compared with 307 tons in 1940.

Philippine Islands.—Exports of manganese ore from the Philippines were 33,664 metric tons for the first 6 months of 1941 compared with 58,038 tons during entire year 1940.

U. S. S. R.—Output in U. S. S. R., the world's largest producing nation, was reported by official sources to have been 2,800,000 metric tons in 1940. It is estimated that production totaled 3,000,000 tons in 1941; no manganese was exported to the United States in 1941.

CHROMITE

By Frederick Betz, Jr.

SUMMARY OUTLINE

GENERAL FEATURES IN 1941

The outstanding features of the chromite industry during 1941 were the continued increase in imports of foreign ore and the expansion of the Government program for purchasing domestic chromite. Mines in the United States shipped 12,731 long tons of chromite (ore and concentrates), a peak in annual shipments for the period since 1918 (see historic table under "Consumption" and fig. 1). The apparent available supply soared to an all-time high of 1,008,507

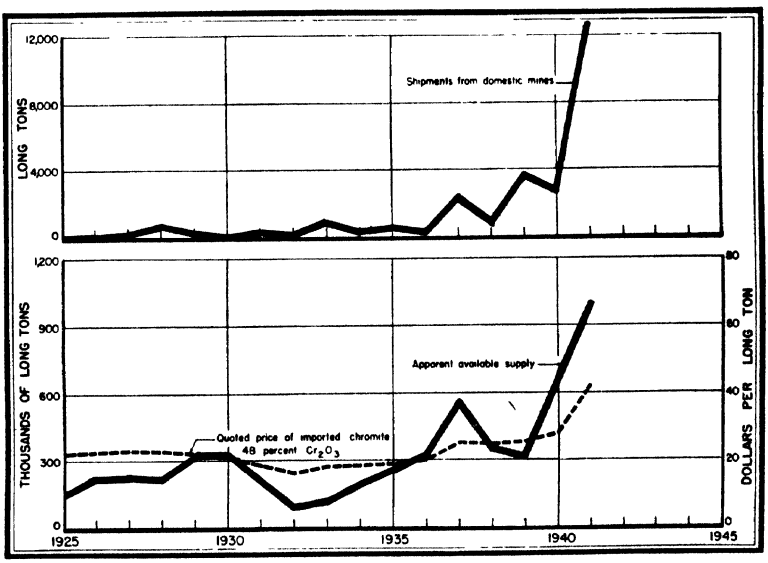

FIGURE 1.—Trends in shipments, prices, and apparent available supply of chromite, 1925–41.

long tons. Large increases were noted in imports from Africa, Cuba, the Philippine Islands, and New Caledonia, whereas shipments to the United States from British India, Greece, and Turkey declined. Statistics on world production are incomplete for 1940 and 1941. Latest figures show that production decreased from 1,155,000 long tons in 1939 to 1,123,000 tons in 1940. In 1941 an increase is indicated, largely because of the rise in exports from Cuba and the Philippine Islands. In the United States, the Government continued its exploration and development work on chromite deposits through the Bureau of Mines and the Geological Survey. The Office of Production Management placed restrictive orders on chromium, which culminated in a complete allocation system. The Metals Reserve Co. established purchasing schedules for domestic ore in November and December to encourage chromite mining in the United States.

Salient statistics of the chromite industry in the United States, 1925–29 (average) and 1937–41

	1925–29 (average)	1937	1938	1939	1940	1941

GOVERNMENT EXPLORATION

In accordance with section 7 of the strategic materials act (53 Stat. 811), the Geological Survey and the Bureau of Mines continued the search for and appraisal of ore deposits containing metals designated as strategic by the Secretaries of War, Navy, and Interior upon the advice of the Army and Navy Munitions Board. The act authorized the expenditure of $500,000 a year—$350,000 by the Bureau of Mines and $150,000 by the Geological Survey—for each of the 4 fiscal years ending June 30, 1940, 1941, 1942, and 1943. The two bureaus are cooperating closely to facilitate accomplishment of the objectives of the act.

In carrying out its part of the program, the Bureau of Mines [1] seeks to determine (1) the extent and quality of the ore, (2) the most suitable method of mining and beneficiating it, and (3) the cost at which it may be produced.

Exploration by the Bureau of Mines [2] of the chromite deposits in Stillwater and Sweet Grass Counties, Mont., carried on in 1939 and 1940 was continued during 1941. Extensive diamond drilling represents

[1] Finch, John W., Strategic Minerals Investigations—Procedure Followed by the Bureau of Mines. Bureau of Mines Inf. Circ. 7097, 1939, pp. 1-5.
[2] Jackson, C. F., Annual Report of the Mining Division, Fiscal Year 1941: Bureau of Mines Rept. of Investigations 3596, 1941, pp. 11-22, 24-25.

the present phase of the investigations, which had been preceded by trenching and large-scale sampling. The Bureau of Mines also conducted examinations in Siskiyou and Glenn Counties, Calif., by trenching and drilling. Special investigations included magnetic and gravimetric surveys of a selected area in the serpentine belt of northern Maryland and southern Pennsylvania, which formerly yielded large supplies of chromite. Drilling will be carried on at selected points.

The Geological Survey mapped in 1941 in considerable detail five chromite deposits in Siskiyou and Tehama Counties, Calif., Skagit County, Wash., and Baranof Island, Alaska. Mapping of the chromite zone of the Stillwater Complex in Stillwater and Sweet Grass Counties, Mont., was continued. In cooperation with the Bureau of Mines, deposits in Siskiyou, Glenn, and San Luis Obispo Counties, Calif., and on the Kenai Peninsula, Alaska, were examined further. Several smaller districts in the United States and Alaska were inspected briefly.

A report [3] was published by the Geological Survey in 1942 on field work performed in connection with the strategic minerals investigations.

The chemical laboratory of the Geological Survey made 52 complete and 143 partial analyses of cleaned chromite from the United States and Alaska, Cuba, Brazil, and other countries of the Western Hemisphere during the years 1939–41.

Investigations of the Metallurgical Division of the Bureau of Mines [4] during the fiscal year 1941 were concerned with the production of high-grade chromium (metal) and standard-grade ferrochromium.

A new method, known as a roasting and leaching process, was developed to convert chromite concentrates into a higher grade of material, which may be used to produce either high-purity chromium or standard ferrochromium for the manufacture of alloy steel. The process is capable not only of increasing the chromium content of the ore but also of raising the ratio of chromium to iron from about 1.7 : 1 to as much as 30 or 40 : 1. In this method, the chromite concentrates are mixed with coke and treated in an especially designed rotary kiln. The material thus treated is cooled, and part of the iron is removed by gravity concentration or by magnetic methods. Additional reduced iron may be removed by leaching with sulfuric acid or sulfur dioxide, leaving the residue enriched in chromium. The Bureau's research indicates that it probably will be most economical to produce a residue having a ratio of 5 parts chromium to 1 part iron. This will permit mixing 2 tons of residue with 1 ton of raw concentrates to produce a product having a chromium : iron ratio of 3 : 1.

A form of sponge, or powdered, chromium (metal) that under certain conditions attains a purity of 99.8 percent—higher than any chromium used in present commercial manufacturing—was also produced from both low- and high-grade domestic chromite.[5] Low-temperature reduction without sintering is the basis of the process. The fundamentals consist in the chlorination of chromite at elevated temperature, the sublimation and separation of volatile chlorides, and the

reduction of the chlorides to metal by hydrogen. The new reduction process may, under favorable circumstances, permit a large amount of low-grade domestic chromite to be utilized at costs comparable with the existing prices of low-carbon ferrochromium. Its future in this field will depend chiefly on the availability and cost of chlorine, the chemical used extensively in producing this new metallurgical material. Its high purity and powdered form are said to render it valuable in the manufacture of special steels, brass and bronze materials, and alloys that are subjected to high temperatures, such as electrical heating elements.

OFFICE OF PRODUCTION MANAGEMENT AND WAR PRODUCTION BOARD

Chromium was one of 16 metals (and classes of metals) subject to inventory control by virtue of General Metals Order 1, issued on May 1, 1941, by the Office of Production Management. In this and subsequent orders "chromium" refers to ores, concentrates, all chromium-bearing products, and scrap, unless otherwise specified.

Chromium was removed from the general order on July 7 and placed under full priority control in Order M–18. The main provisions of this order were the following:

1. All defense orders were assigned a preference rating of A–10 unless higher ratings were specifically given.
2. Monthly deliveries of chromium to be used in the manufacture of chemical products were limited to the average monthly consumption of the processor during the 12 months preceding June 30, 1941
3. Deliveries by processors of chromium refractory material were allowed only under defense orders or for necessary maintenance and repairs, except under other authorization.
4. Deliveries for nondefense purposes were permitted after fulfillment of all other terms of this order.
5. Restrictions against accumulation of excessive inventories were also established.

An amendment to Order M–18 became effective August 22. This statement was chiefly a clarification and redefinition of certain terms and provisions of the original order. The monthly use of chromium in ores and concentrates for production of chemicals was limited to a quantity of chromic oxide not greater than one-twelfth of the total annual consumption of oxide for this purpose by the processor during the period from July 1, 1940, to June 30, 1941. Acceptance of defense orders was made compulsory, subject to certain provisions.

Order M–18–a was issued on November 29, revoking the previous chromium orders. The new order included two main provisions:

1. Complete control of deliveries of chromium was placed in the hands of the Director of Priorities. Monthly requests for delivery of chromium were required to be made to producers.
2. The total chromic oxide content of ore to be used by any processor in the manufacture of chromium chemicals during any month was limited to one-twelfth of the aggregate oxide content used in chromium chemicals actually delivered by the processor during the period from July 1, 1940, to June 30, 1941.

On January 13, 1942, an amendment to Order M–18–a prohibited any person from melting more than 2 tons of ferrochrome in any month without specific authorization. The amendment was designed to conserve chromium steel for military needs. A further amendment was added on February 4, in which a complete allocation system for chromium (including scrap) was established. It was also stated therein that chromium could be melted only with specific permission.

Order M–18–b, effective March 26, 1942, limited the use of chromium in chemicals (including chromium for pigments, chromic acid, leather tanning, and wood preservation). The use of chromium in the manufacture of roofing materials, ceramics, soap, and glass was prohibited.

Chromium steel was subjected to regulation in Order M–21, relating to priority control over steel, first issued on August 9, 1941, and amended September 9. It was also included in Order M–21–a (September 16) and dealt with specifically in an amendment dated November 25. This last prohibited the manufacture and delivery of alloy iron or steel containing 4 percent or more chromium, except on preference ratings of A–10 or higher. Order M–21–d of December 27 provided that no person shall consume, fabricate, or deliver corrosion- or heat-resistant alloy iron or steel containing over 4 percent chromium after January 6, 1942, except on ratings of A–10 or higher. An amendment to this order, issued March 27, further restricted the use of steel with 4 percent or more chromium to orders with priority ratings of A–1–k or higher.

Chromium was one of the 13 materials listed in General Imports Order M–63, which provided that, as of December 28, 1941—

Unless otherwise authorized by O. P. M., all future contracts for imports of these materials will be handled by the Metals Reserve Co., R. F. C. subsidiary, or other governmental agency. No private person or concern can make arrangements for imports, except that in certain cases, such as imports for processing and immediate reexport, the Director of Priorities may grant specific exceptions to the Order.

METALS RESERVE COMPANY

On November 1, 1941, it was announced that the Metals Reserve Co. would consider contracts for the purchase of domestic chrome ore with a minimum Cr_2O_3 content of 40 percent. A memorandum detailing terms of contracts, quantity of ore, grade specifications, prices, shipments, and payments was released November 14. The purchasing schedule was revised December 19, 1941, and February 20 and May 25, 1942. An abstract of the schedule of May 25 follows:

1. *Quantity:* 1,000 to 10,000 long tons per contract. Contracts in excess of 10,000 tons may be obtained as a result of individual negotiations, provided reliable and complete engineering data submitted by the applicant warrant a contract for a larger quantity.
2. *Terms of contract:* Deliveries must be completed within 18 months of date of contract. If delivery of 20 percent of the tonnage contracted for has not been made within 6 months of date of contract, Buyer (Metals Reserve Co.) may cancel contract forthwith.
3. *Quality:* Purchases of domestic chrome ores will be of three grades, with the following specifications:

	High-Grade	Low-Grade	
		A	B
Cr_2O_3 .... percent minimum	45.00	40.00	40.00
SiO_2 .... percent maximum	11.00	13.00	None
P .... do	.20	.50	None
S .... do	.50	1.00	None
Cr : Fe ratio .... minimum	2.5:1	2.0:1	None

Under Low-Grade A and B, chrome ore will be accepted to 35 percent minimum under penalties described below.

4. *Size of ore:* None in excess of 12 inches.

Buyer may reject any shipment which does not conform to the applicable requirements and specifications as set forth above.

5. *Price:* Effective May 25, 1942, contracts will be considered on the following schedule for domestic ores within the continental United States (excluding Alaska); all prices per long ton (2,240 pounds) of dry weight, f. o. b. cars at stock pile designated by Buyer.

High-Grade—Base price: $40.50 per long dry ton for ore containing 45 percent Cr_2O_3, and with a ratio of chrome (Cr) to iron (Fe) of 2.5 : 1; with an increase of 90 cents per ton for each unit Cr_2O_3 in excess of 45 percent Cr_2O_3; with an increase of $1.50 per ton for each tenth increase in chrome : iron ratio to a maximum of 3.0 : 1.

Low-Grade A—Base price: $28.00 per long dry ton for ore containing 40 percent Cr_2O_3, with a ratio of chrome (Cr) to iron (Fe) of 2.0 : 1; with an increase of 90 cents per ton for each unit Cr_2O_3 in excess of 40 percent Cr_2O_3; with an increase of $1.50 per ton for each tenth increase in chrome : iron ratio to a maximum of 3.0 : 1. Chrome ore containing a minimum of 35 percent Cr_2O_3 but otherwise meeting the specifications set forth for this grade will be accepted with a penalty of $1.40 per long dry ton for each unit (22.4 pounds of Cr_2O_3) under 40 percent.

Low-Grade B—Base price: $24.00 per long dry ton for ore containing 40 percent Cr_2O_3, with an increase of 60 cents per ton for each unit Cr_2O_3 in excess of 40 percent Cr_2O_3. Chrome ore containing a minimum of 35 percent Cr_2O_3 but otherwise meeting the specifications set forth for this grade will be accepted with a penalty of $1.20 per long dry ton for each unit (22.4 pounds of Cr_2O_3) under 40 percent.

Fractions prorated in all cases.

In addition to the above prices, an allowance will be made for each long ton shipped equal to the freight tariff per long ton from Seller's nearest convenient rail station to Buyer's stock pile.

The cost of sampling and analysis by the Buyer, weighing, and unloading onto stock pile will be for the account of Buyer.

Each lot of ore will be graded in accordance with the specifications heretofore set forth (all elements to be within the range specified for the applicable grade), and the price to be paid for such ore will be governed accordingly.

6. *Shipment and Delivery:* Seller will give such advice regarding shipment and arrival as Buyer may require, at least 10 days prior to shipment of the ore from point of loading onto railroad cars; otherwise, any demurrage at the stock pile will be for Seller's account.

Shipment will be made in flat-bottom gondolas, if available, in lots of not less than 1 carload, to the stock pile designated by Buyer. Seller will prepay the freight to such stock pile, where the ore will be weighed in cars, light and loaded, on track scales, and sampled for moisture. The lot will be sampled as unloaded and upon receipt of analysis, Buyer will advise Seller as to whether the ore is acceptable and under what classification.

If the lot is ascertained to be unacceptable under the above specifications, Seller will not be entitled to any allowance for prepaid freight and will be held responsible for the removal of this shipment of ore from the stock pile location. Upon failure so to remove the ore within 15 days of due notice, Buyer may, at its absolute discretion, remove such ore and the cost of such removal shall be for Seller's account; or Buyer may, at its option, otherwise dispose of such ore without any liability therefor. In the event that Seller fails to repay Buyer, within 15 days after notice, for the cost of removal, Buyer may cancel the contract forthwith.

7. *Payment:* As soon as moisture and analysis determinations are received, Buyer will promptly pay Seller in accordance with the weight certificate and the above schedule.

8. *Weights:* The weight paid for will be net railroad track scale weights (weight of loaded car less weight of empty car), less moisture as determined by standard practice.

9. *Sampling and Analysis:* Each lot will be sampled at the time of unloading onto stock pile by a sampler designated by Buyer, three samples being taken, one each for Seller, Buyer, and Umpire, and analysis made for chrome and other guaranteed elements. Usual provisions will be made for splitting limits and settlement by average of Seller's and Buyer's analyses, or by trade practice if samples are sent to Umpire. Moisture samples will be taken in accordance with standard practice. Seller may have representative at sampling at his own expense.

To stimulate production from small chromite deposits in Oregon and northern California and to provide a ready market for the ore, the Metals Reserve Co. announced on March 5, 1942, that truckload lots of ore mined in these localities would be purchased. Purchase depots, at which agents are located, were provided at Coquille, Grants Pass, and Seneca, Oreg., and at Yreka, Calif., and others are being established. Ore or concentrates delivered at the depots will not be accepted as delivery on contracts made under earlier schedules. This buying plan became effective April 1, 1942, for 1 year. Grade specifications and prices are the same as in the May 25 schedule summarized above. Payment will be made as soon as lots of 10 tons or more have been delivered and analyzed.

DOMESTIC PRODUCTION

The domestic output of chromite, in terms of shipments from mines, totaled 12,731 long tons in 1941 compared with 2,662 tons in 1940. Shipments in 1941 were the largest in any year since 1918. A table showing annual shipments of chromite from mines in the United States from 1910 to 1941 is given in the section of this report on "Consumption."

California and Oregon were the only States from which chromite was shipped in 1941; the former furnished the bulk of the total. Most of the chromite shipped from California came from properties in Del Norte, Eldorado, Fresno, Humboldt, and Placer Counties. The largest individual source was the Pilliken mine in Eldorado County, operated by the Rustless Mining Corporation; the concentrates produced from Pilliken ore averaged 43 percent Cr_2O_3 and 26 percent FeO in 1941. The second most important property, in quantity shipped, was the High Plateau mine in Del Norte County, operated by Eugene R. Brown. In Oregon, chromite was shipped from mines in Curry, Jackson, and Josephine Counties.

Extensive development work was reported from various localities. In California especially a large number of properties were stated to be under development, and in some places ore was mined but not shipped. Some of the larger projects undertaken during 1941 are summarized as follows:

In Montana, the Anaconda Copper Mining Co. developed a mine in the deposits of Stillwater County and constructed a mill. Shipments of concentrates were to begin early in 1942. The project was carried out by the Anaconda company at the request of the Office of Production Management and the Metals Reserve Co., with funds provided by the Reconstruction Finance Corporation. Under a similar arrangement with the Government, the company will develop and equip further mines and mills in the Stillwater area. The United States Vanadium Corporation began a chromite mining and milling operation in Carbon County, Mont. A mill with an initial capacity of 200 tons a day was under construction at Red Lodge, and ore for milling was being hauled from the mine to the mill site in 1941.

In California, the Rustless Mining Corporation began to build a 200-ton mill in Glenn County to concentrate ore from the Gray Eagle mine.

In Oregon, the Krome Corporation, which plans to concentrate chromite from black beach sands, undertook to construct a plant near Port Orford in Curry County.

[1] Small quantity of ore containing 35 to 45 percent chromic oxide included with ore containing 45 percent or more.
[2] Includes small quantity of ore containing less than 35 percent chromic oxide.

IMPORTS [6]

Imports of chromite in 1941 reached a new peak, exceeding the previous high of 1940 by 51 percent. Despite war conditions, which hampered shipping throughout the world, the principal foreign sources of chromite continued to furnish large supplies. The only notable decrease was in shipments from British India, Greece, and Turkey. The imported chromite averaged 45 percent Cr_2O_3 in 1941, as compared with 46 percent in 1940. The imports from New Caledonia had the highest chromic oxide content (52 percent), and those from Cuba had the lowest (35 percent).

The following table shows imports of chromite into the United States, 1937-41, by countries; and a table showing annual imports from 1910 to 1941 is given in the section of this report on "Consumption."

Crude chromite imported for consumption in the United States, 1937-41, by countries

Country	Gross weight (long tons)				1941

[1] Originated in Southern Rhodesia and Union of South Africa; recorded by the Department of Commerce as imported from Union of South Africa, "Other British South Africa," "Other British West Africa," and Mozambique.

[6] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

No imports of chromium compounds were recorded in 1940 or 1941; a table showing imports of these compounds from 1937 to 1939 is given in Minerals Yearbook, Review of 1940, page 591.

The following table shows imports of ferrochromium and chromium into the United States from 1937 to 1941.

Ferrochrome or ferrochromium and chrome or chromium metal imported for consumption in the United States, 1937–41, in long tons

Class	1937	1938	1939	1940	1941
Ferrochrome or ferrochromium—					
Containing 3 percent or more carbon (chromium content)	96	(1)	3	(2)	79
Containing less than 3 percent carbon (chromium content)	164	121	127		
Chrome or chromium metal	78	39	56	(3)	

[1] 60 pounds. [2] 1,020 pounds. [3] 1,000 pounds.

PRICES

Nominal prices of chromite for import are quoted in domestic trade journals in dollars per long ton, c. i. f. North Atlantic ports. At the beginning of 1941, Engineering and Mining Journal Metal and Mineral Markets quoted Indian and African 48 percent metallurgical ore at \$32 to \$34. The price rose during the year and in September reached \$47 to \$49; during the last quarter, it held at \$45 to \$47. Refractory ore (43 to 45 percent) opened the year at \$22 to \$24 and increased to \$30 to \$32, a price that was maintained for the last 4 months of 1941.

Prices for domestic chromite were established by the Metals Reserve Co. in its schedule of November 14 and revised on December 19. The following were the base prices per long dry ton, f. o. b. stock pile designated by the Metals Reserve Co.:

November 14:	
48 percent Cr_2O_3, Cr · Fe=3·1	\$43.20
40 percent Cr_2O_3	22.00
December 19:	
45 percent Cr_2O_3, Cr : Fe=2.5:1	40.50
40 percent Cr_2O_3, Cr : Fe=2:1	28.00
40 percent Cr_2O_3, no Cr : Fe ratio specified	24.00

CONSUMPTION

Consumption of all grades of chromite in the United States during 1941 amounted to 714,645 long tons. Actual data on consumption have not been published before, but at the close of 1940 the annual rate was reported to be about 600,000 tons. For purposes of comparison, the apparent available supply may be used as an indicator of the requirements in the years preceding 1941. Since institution of the Government purchasing program, part of the new supply—comprising shipments from domestic mines and imports for consumption—has entered Government stock piles, from which an undisclosed quantity has been released to consumers. The following table, covering the period from 1910 to 1941, shows the general upward trend in apparent supply of chromite and reflects the increasing demand. During World War I, domestic production constituted a significant

source of supply, but since 1920 virtually all the chromite consumed in the United States has been imported.

Domestic production, imports, and apparent available supply of chromite in the United States, 1910–41

Year	Domestic production (shipments from mines)					Imports (long tons)	Apparent available supply [1] (long tons)
	Long tons				Total value		
	California	Oregon	Other States [2]	Total			
1910	205			205	$2,729	38,579	38,784
1911	120			120	1,629	37,540	37,660
1912	201			201	2,753	53,929	54,130
1913	255			255	2,854	65,180	65,435
1914	506		85	591	8,715	74,686	75,277
1915	3,281			3,281	36,744	76,455	79,736
1916	43,758	3,099	178	47,035	726,243	115,945	162,980

[3] According to Division of Mines and Mining, Department of Natural Resources, California

Over 80 percent of the chromite supply is consumed in the steel industry, either as a source of the alloying element chromium or in refractories. Stainless steel has been one of the principal chromium-bearing products, of which important quantities were used by the automotive industry. In 1940 nearly 60 percent of the total metallurgical ore consumed was in stainless steels.[7]

USES

The industrial uses of chromite are classified in three groups: Metallurgical, refractory, and chemical. For use in making alloy steels chromite is generally first converted into ferrochromium, an alloy containing 60 to 70 percent chromium, before being added to the steel bath. Ferrochromium is produced in high- and low-carbon grades. On December 17, 1941, the Office of Production Management announced that all domestic producers of ferrochromium had agreed voluntarily to change specifications for the high-carbon in order to permit the use of lower-grade ores and to conserve the higher grades.

[7] Advisory Committee to W. P. B. on Metals and Minerals, Ferrous Minerals and Ferro-Alloys Group, Chrome Ore, Its Conservation and Substitution: Metal Prog., vol. 41, No. 4, April 1942, pp. 503–506.

The new specifications are approximately the same as those in use during World War I. The specifications—formerly 68 to 69 percent Cr, 4 to 6 percent C, and 1 to 2 percent Si—are now 60 to 63 percent Cr, 6 to 8 percent C, and 4 to 6 percent Si.

One solution of the problem of using low-grade ores for metallurgical purposes is offered by Udy,[8] who has developed "Chrom-X," a product being manufactured in high- and low-carbon grades. The use of "Chrom-X" in the production of chromium steels was described by McDonald.[9]

Chromium plating constitutes an important industrial application of this element, although small quantities are consumed. Chromic acid is the raw material for this purpose. A review by Hall [10] of latest research in this field shows that "hard" chromium plating was the principal object of studies during 1941.

The "Inkrom" process [11] of chromium impregnation of iron and steel surfaces was discussed by Rudorff,[12] who reported that it is in full commercial use in Germany. The process involves the introduction of gaseous chromium chloride to the surface to be treated. The surface zones of chromised materials assume properties similar to those of rustless steel. Important fields of application of the process are in the manufacture of turbine blades, tubing, bolts, and screws.

For refractory purposes certain grades of chromite in the form of lump or ground ore may be used directly. Chromium cements, plastics, and bricks are also produced for similar uses. At present about 6 pounds of chromite are consumed as a refractory in the production of each ton of steel.[13]

Chromium chemicals are used in dyeing, tanning, and pigments and in pickling solutions in nonferrous-metals industries.

WORLD PRODUCTION AND TRADE

Statistics on world production of chromite in 1941 are incomplete, but available data indicate that the output was greater than in 1940. The United States, as the leading consumer of chromite, depends largely on imports for its supply. The record attained in 1941 in imports, which amounted to 1,011,758 metric tons, gives strength to the belief that world production increased, although some of the imports may have come from stocks in foreign countries. The following table shows the Philippine Islands and Cuba as the chief producers of chromite in 1941; however, estimates of the output from Southern Rhodesia and U. S. S. R. suggest that these countries should be considered among the leaders in chromite production.

[7] January to November, inclusive.
[8] January to October, inclusive

Most of the world output of chromite enters international trade, as the principal producing countries are not important consumers. Notes concerning countries that produce and consume chromite and developments of potential sources follow:

Brazil.—The Cascabulhos mine, 12 miles west of Campo Formosa in the State of Baía, was the only active chromite producer in 1941. The concentrates average about 48 percent Cr_2O_3 and have a Cr:Fe ratio of 2.9:1. Shipments of chromite were also made from an old stock pile at Santa Luzia, Baía.

Chromite was included in the list of strategic or critical minerals specified in an agreement between the United States and Brazil whereby the United States contracted for all of Brazil's production during the next 2 years. The United States Government will purchase any ore not taken by private American buyers.

Canada.—The Sterrett chromite property at St. Cyr, Quebec, which produced considerable quantities of chromite during World War I, was reopened and was said to be producing at the rate of 100 tons a week at the end of 1941. Ore reserves were estimated at about 20,000 tons, averaging 28 percent chromite. Chromite, Ltd., now operating the property, began to construct a 50-ton concentrator late in September. Exploratory work was carried on in Quebec and British Columbia The Government was reported to have begun an investigation of chromite possibilities in the Black Lake area, Eastern Townships, Quebec.

Cuba.—At Moa, Province of Oriente, exploitation of chromite deposits was begun; reserves are estimated at 150,000 tons. Cuba's entire output of chromite is shipped to the United States. Imports

into the United States were 163,222 metric tons in 1941 compared with 52,789 tons in 1940.

Germany.—An important consumer of chromite, Germany depends on foreign sources of supply. At present, sources within Europe and Asia Minor appear to be the only ones to which Germany can look. About 100,000 tons of chromite have been produced annually in the Balkans, principally from deposits in Yugoslavia and Greece. Bulgaria has a small output, and Rumania has deposits that were exploited by the German Army during the first World War.[14] It may be assumed that chromite mined in Norway, a minor producer, will also be available to Germany. As a result of a trade agreement, Germany is to obtain 90,000 to 100,000 tons of chromite from Turkey in both 1943 and 1944.

India.—Virtually all of India's chromite output has been exported. Nearly one-half of the production comes from Mysore State, and about one-third is furnished by the Hindubah mines near Quetta. Curtailment of foreign supplies of bichromates led to the opening of the Pioneer Chromate Works at Andheri, equipped to produce 400 long tons annually. Imports of most chromium compounds are subject to license control, and certain restrictions have been placed on the use of such compounds.

New Caledonia.—Early in 1941 the Free French Government of New Caledonia prohibited the exportation of chromite to Japan. The Tiébaghi mine, one of the richest chromite mines in the world, was reported to be making shipments to the United States at the rate of about 7,500 tons monthly. The Fantoche mine had shipped its entire stock to the United States by the end of July, but exports were to be resumed early in 1942. A brief review of chromite deposits in New Caledonia was given by Priday.[15]

Newfoundland.—Development work continued on the recently discovered chromite deposit in the Lewis Hills on the north side of Fox Island River, near Port-au-Port Bay, western Newfoundland. Irregular lenses of ore occur in a zone about 1,200 feet long. Based upon diamond drilling to shallow depths, the ore reserves were estimated at almost 12,000 tons averaging 37 percent Cr_2O_3.

Philippine Islands.—According to Boericke,[16] approximately half of the Philippine chromite exports are of refractory-grade ore, all from the Masinloc deposit in Zambales Province. The remainder is high-grade ore, mostly from the Acoje Mining Co. property at Santa Cruz, Zambales. A new operation in Oriental Misamis, Mindanao, yielded about 14,000 tons of ore averaging over 50 percent Cr_2O_3. Frasché[17] estimates the chromite reserves in the Philippine Islands to be 10,890,500 metric tons, of which 10,120,000 are of refractory grade, 450,500 of chemical grade, and 320,000 of metallurgical or submetallurgical ore.

Southern Rhodesia.—Rhodesian Chrome Mines, Ltd., of Bulawayo, and the affiliated African Chrome Mines, Ltd., of Salisbury, are reported to be producing 90 percent of the chromite output of the country from the Selukwe district. The Southern Rhodesian produc-

tion, now thought to be proceeding at the rate of about 325,000 tons a year, represents the full capacity of the mines.

Turkey.—Late in 1939 Turkey ceased exporting to Germany, principal purchaser of Turkish chromite before the war. Since then shipments have been made to the United States, England, and France. Following the collapse of France in 1940, Great Britain obtained that country's share of the output. During 1941 Germany concluded trade negotiations with the Turkish Government, and it was indicated that 90,000 to 100,000 tons of ore would be furnished in both 1943 and 1944, contingent upon the delivery by Germany of war materials to the extent of £T18,000,000 before 1943. Subsequent deliveries of ore were to be made only upon receipt of German war materials of equal value.

United Kingdom.—In October 1941 it was announced that the Chrome Ore Control would henceforth purchase all chromite (ore and concentrates) required in the United Kingdom. Consumers will make their applications to the Control for quantity and quality of ore desired. The Control will undertake to deliver the chromite to consumers and establish price schedules for all grades delivered at consumers' plants. No licenses are necessary for such purchases. The decision of the Government to purchase chromite was prompted by the inequitable distribution to consumers during periods of freight shortage. A strain on internal transportation facilities had also been caused by transfers of ore between plants in Great Britain. Early in 1942 the Ministry of Supply decided that chromium plating for a wide variety of purposes would be discontinued in consideration of the great demand for chromic acid.

NICKEL

By H. W. Davis

SUMMARY OUTLINE

Although world production of nickel reached an all-time high in 1941, the supply available fell short of the unprecedented demands for nickel for war purposes of the United Nations. As a consequence, peacetime industrial consumers had to curtail sharply their use of nickel steels and other nickel-bearing products. On March 7, 1941, primary nickel deliveries and allocations in the United States were placed under priority control by the Office of Production Management. The United States consumed over two-thirds of the total world nickel available in 1941, of which steel mills used about 70 percent and nonferrous rolling mills most of the remainder.

Although figures are not obtainable, Canada undoubtedly furnished a larger proportion of the world nickel supply than in 1940. The International Nickel Co. of Canada, Ltd., and Falconbridge Nickel Mines, Ltd., have extensive expansion programs under way that will further increase the nickel supply.

[1] Figures not yet available.
[2] Excludes "All other manufactures of nickel"; weight not recorded.
[3] Excludes "Manufactures"; weight not recorded.
[4] Price quoted by International Nickel Co. of Canada, Ltd., for electrolytic nickel at New York, in 2-ton minimum lots.
[5] Excludes small quantity produced in British Columbia.

In 1941, as usual, the domestic production of primary nickel was insignificant. In addition to the nickel produced as a byproduct in the electrolytic refining of copper and as secondary nickel, comparatively small quantities were produced from ore mined in Colorado and as a byproduct of talc production in Vermont.

Continuing the search for ore deposits of strategic metals, as authorized under section 7 of the Strategic Materials Act, the Bureau of Mines completed diamond drilling of a large body of low-grade copper-nickel ores in Stillwater County, Mont. This drilling aggregated 5,981 feet, which, taken in conjunction with earlier drilling and underground exploration by a commercial company, revealed a few million tons of material averaging 0.4 percent nickel and 0.37 percent copper. Exploration of low-grade deposits on Yakobi Island in Alaska included the completion of two diamond-drill holes which indicated material of about the same average grade as that exposed in surface outcrops. This work was recessed on account of severe weather conditions, to be resumed in the spring of 1942.

As part of its program of investigation, the Geological Survey published reports describing the nickel deposits on Yakobi Island, Alaska; near Riddle, Douglas County, Oreg.; and near Mount Vernon, Skagit County, Wash.

According to Reed and Dorr: [1]

Calculations based on the investigations made by the Geological Survey in 1940 indicate that about 6,000,000 tons of rock, containing about 0.36 percent of nickel and 0.27 percent of copper, is present and available for mining in the eight bodies that have been partly prospected. Further prospecting will probably greatly increase the estimate of the tonnage available in the bodies, but it probably will not greatly change the estimate of the grade. Rough calculations indicate that the material can be mined and the nickel and copper extracted from it at a cost roughly equal to the value of the metals that would be produced.

Concerning the nickel deposit near Riddle, Douglas County, Oreg., Pecora and Hobbs [2] write:

About 162 acres of ground are underlain by a blanket containing over 6,000,000 tons of material, 1 to 2 percent of which is probably nickel. Eighty thousand tons have been proved to contain 2 to 3 percent of nickel, and 75,000 tons have been proved to contain 1 to 2 percent of nickel. A new method of treating low-grade silicate material would have to be devised before this large deposit could be utilized.

The following paragraph is quoted from a report by Hobbs and Pecora: [3]

The silica-carbonate rock on Devils Mountain cannot properly be considered a large potential nickel reserve. At best, if selective large scale low-cost mining methods and favorable means of concentration are employed, it might be considered a marginal to submarginal gold deposit, whose value would be slightly enhanced by the small amount of nickel recoverable from the sulfide minerals of the concentrates. The sulfide-bearing breccia, because of its uneven tenor and small tonnage, cannot be depended upon to sustain any long mining operation. Some of it, however, might be mined at a profit under present economic conditions. This sulfide ore could best be mined selectively, on a small scale, and concentrated by flotation, to which the ore is well adapted.

PRODUCTION

Domestic production of nickel is small and comprises secondary metals recovered from scrap-nickel anodes, nickel-silver, and copper-

nickel alloys (including Monel metal) and primary metal recovered in copper refining and produced from ore and as a byproduct of talc production, as listed in the following table. Domestic primary nickel is recovered as a byproduct in copper refining at Baltimore, Md., Laurel Hill, N. Y., Perth Amboy, N. J., and Tacoma, Wash. A matte containing 22.58 percent nickel, 4.28 percent copper, and 1.46 percent cobalt was produced in 1941 from ore mined near Gold Hill, Colo. Concentrates containing 13.39 percent nickel and 1.27 percent cobalt were recovered as a byproduct of talc production in Vermont in 1941.

Nickel produced in the United States, 1937–41

Year	Primary (short tons) [1]		Secondary [2]	
	Byproduct in copper refining [3]	Other [4]	Short tons	Value
1937	219		2,400	$1,680,000
1938	416		2,300	1,610,000
1939	394		2,920	2,044,000
1940	554		5,150	3,605,000
1941	619	41	(5)	(5)

[4] Nickel content of matte produced from ore and of concentrates produced as a byproduct of talc.
[5] Figures not yet available; they will be found in the chapter on Secondary Metals—Nonferrous.

FOREIGN TRADE[4]

The nickel imported into the United States in 1941 comprised chiefly metallic nickel and nickel alloys, matte, and oxide. All the oxide, 63,220,793 pounds of the matte, and 149,447,516 pounds of the metallic nickel and alloys were obtained from Canada; virtually all the remainder of the matte (16,671,607 pounds) came from New Caledonia; and the rest of the metallic nickel and alloys (539,406 pounds) came from Europe, chiefly the United Kingdom (538,931 pounds). The matte from Canada, which contains approximately 55 percent nickel and 25 percent copper, is refined to Monel metal and other products at the plant of the International Nickel Co., Inc., Huntington, W. Va. The matte from New Caledonia, which contains about 77 percent nickel, will also be refined at Huntington, where a new plant has been provided primarily for refining raw material from New Caledonia and elsewhere. The nickel content of the unmanufactured nickel products imported into the United States is estimated at 212,363,000 pounds in 1941, as compared with 167,519,000 pounds in 1940. Imports of nickel in 1941 were the largest on record.

Exports of nickel comprise largely products manufactured from imported raw materials. Exports of all classes except nickel silver decreased substantially. The United Kingdom (6,021,581 pounds) was the chief market for nickel, Monel metal, and other alloys in 1941.

[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

WORLD PRODUCTION

Because of Government restrictions on the publication of statistics for many countries, few figures for 1940 and 1941 are available; however, production during 1941 was the largest on record.

World production of nickel (content of ore), 1937–41, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

[1] In addition to countries listed, Japan also produces nickel, but data of output are not available.
[2] Data not yet available.
[3] Excludes small quantity produced in British Columbia.
[4] Estimated.
[5] Byproduct in electrolytic refining of copper.
[6] Includes also a small quantity produced from ore and as a byproduct of talc.

Brazil.—The nickel deposits at São José do Tocantins, State of Goyaz, and at Livramento, State of Minas Geraes, have been described in considerable detail by Wright and Pardee.[5]

The nickel deposit at Jacuba, São José do Tocantins, occurs at an altitude of 800 meters on the west side of Serra do Mantiqueira. An automobile road 2 miles long extends from Jacuba to the mine workings, which are at an elevation of 1,050 meters; cobalt is also being mined. Anapolis, the nearest railroad station, is 220 miles from the mine over a narrow, ungraded road, and at present it is necessary to ferry across the Maranhao River. Estimates of ore reserves range from 20 to 100 million tons. Much work will have to be done before the economic limits of the ore body can be outlined accurately enough to permit making tonnage estimates. Assays of numerous samples show a nickel content ranging from 3 to 12 percent, the average being about 5 percent. Mining conditions are favorable, as gravity can be used both in mining and transporting the ore to the mill. The ore could be mined by open-cut, or the millhole system could be used by mining the ore at the surface into raises to an adit level below, with a bulldozing chamber near the bottom of each raise to reduce the large pieces before loading them into ore cars. As the ore is relatively soft, large tonnages could be mined per man-shift with a low consumption of explosives, power, and timber. One of the immediate problems is concentrating the ore. A reverberatory furnace costing $50,000 was installed at Jacuba to reduce the ore to nickel matte, but the company could not obtain the necessary pyrites or gypsum for its operation. The furnace was designed to burn wood, and charcoal and limestone were to be fed into the furnace with the ore and sulfur or pyrites. Concentration of the ore by flotation and leaching methods is to be studied thoroughly. Both water supply and power for a mill are available from nearby rivers, and there are a number of excellent mill sites in the immediate vicinity, with adequate room for tailings disposal.

The Livramento nickel deposit occurs at an altitude of 1,100 meters and is 225 kilometers north of the port of Angra dos Reis, with which it has a direct railroad connection. The mine is operated by the Companhia de Nickel do Brazil, which produces ferronickel in an electric furnace capable of smelting about 15 tons of ore daily. The nickel content of the ore as mined ranges from 1 to 3 percent. During 1936, 28,000 tons of nickel ore were mined; 18,000 tons of this total were shipped to Germany, 7,000 tons went to the company furnace, and 3,000 tons were left in stock. Mine output for the first 4 months of 1941 totaled 1,667 tons. The company produced 492 metric tons of 20-percent ferronickel from the time that the plant was started (in 1939) through 1940. Output of ferronickel for the first 4 months of 1941 was 153 tons, most of which is reported to have been shipped to Germany. The 1942 production will be sold in Brazil—200 tons to the Companhia Siderurgica Belgo Mineira and the rest to smaller steel plants.

Canada.—Virtually all the Canadian output is derived from the copper-nickel ores of the Sudbury district, Ontario; and two companies—International Nickel Co. of Canada, Ltd., and Falconbridge Nickel Mines, Ltd.—are the principal producers. Although figures are

[5] Wright, C. W., and Pardee, F. G., The Nickel-Cobalt Deposit at São José do Tocantins, State of Goyaz, Brazil: Ms. Rept., June 4, 1941, 22 pp.; The Nickel Deposit at Livramento, Minas Geraes, Brazil: Ms. Rept., June 14, 1941, 10 pp.

not available, the output in 1940 and 1941 surpassed the former record output of 113,053 short tons in 1939.

The International Nickel Co. of Canada, Ltd.,[6] operated its mines, smelters, and refineries continuously, largely upon a 24-hour basis. Production of nickel reached an all-time high, and additional works are being constructed that will increase the output further.

Falconbridge Nickel Mines, Ltd.,[7] attained higher annual levels, in both tonnage treated and in production, in 1941, than in any previous year. Part of the gain was attributed to the installation of some additional equipment in the mill but was accomplished mainly by crowding all units to the limit. Extensive additions have been undertaken in various units of the plant to provide for increased capacity.

Cuba.—According to an announcement by the War Production Board, large deposits of the low-grade ores of northeastern Cuba are to be treated by a complicated chemical and metallurgical process to yield nickel by the Nicaro Nickel Co., a new subsidiary of the Freeport Sulphur Co., which since early 1940 has conducted research on nickel recovery. A pilot plant was put into operation in late August 1941. A 20-million-dollar plant and facilities have been authorized; construction is being financed by Reconstruction Finance Corporation, and the plant will be operated by Nicaro Nickel Co. for the Government.

Finland.—According to the Northern Miner: [8]

It is learned that the Germans have placed the mine [Petsamo] in production of ore at the rate of 300 to 350 tons a day, that this ore is being sent to the Norwegian port of Kirkenes, and from there freighted down the coast to Germany. It is being direct-treated in the former Mond I. G. plant at Frankfurt by a process that recovers perhaps half the nickel content and supplies Germany with refined nickel at the rate of 5 million pounds a year.

New Caledonia.[9]—The largest nickel-producing centers are at Thio on the east coast and Voh and Koné on the west coast, all operated by the Nickel Society, whose large Noumea smelters are on the site of former cobalt smelters erected in 1894. The company also erected smelters, using hydroelectric power, at Yate on the southeast end of the island; these were closed in 1931 when the company amalgamated with the Société Hauts Fourneaux, which was then operating the Noumea smelters. In addition to the Nickel Society holdings, hundreds of mines are owned by individuals, but only a dozen or so of these are working; in 1940 they produced about one-third of the Colony's ore. Some of this ore is bought by the Nickel Society; the rest has been exported to Japan. Before the war, Germany bought nickel ore containing 4.7 percent nickel to mix with her own low-grade ore. Ore containing as low as 3.5 percent nickel was being shipped to Japan up to the end of 1940, when the ban on export came into operation.

COBALT

By H. W. Davis

SUMMARY OUTLINE

The consumption of cobalt in the United States, chiefly in the production of high-speed cutting tools and permanent magnets, increased substantially during 1941; as heretofore, most of the demand was supplied by imports, mainly in the form of residues from Belgian Congo. Though comparatively small, domestic production made large proportionate gains in 1941, and most of it was a byproduct of the iron ore mined at Cornwall, Pa. The greater part of the cobalt-bearing residues from Belgian Congo is converted to metal at Niagara Falls, N. Y., and to oxide, sulfate, catalytic salts, or driers at Cincinnati and Cleveland, Ohio; Elizabeth, N. J.; New Brighton, Pa.; and Richmond, Calif. The metal-refining capacity of the Niagara Falls plant is being increased 50 percent. Most of the Canadian cobalt ore imported into the United States is processed to oxide and other commodities at Cincinnati. Cobalt oxide was also produced in 1941 at Wilmington, Del., from cobalt-containing pyrites concentrates recovered from the iron ore mined at Cornwall, Pa. Production of metal at Wilmington is planned for 1942. A mixed oxide of nickel and cobalt was recovered in 1941 from Burmese nickel speiss in a plant at Cleveland.

Domestic quotations for metal in 100-pound lots and for black oxide in 350-pound lots remained unchanged throughout 1941 at $1.50 and $1.84 a pound, respectively. These prices have been in effect since the latter part of October 1939.

General Preference Order M–39, issued by the Office of Production Management on November 4, 1941, placed cobalt ore and residues, metal, and cobalt chemical compounds under an allocations system to insure priority for war uses and also limited deliveries of cobalt chemical compounds for nonmetallic uses to 90 percent of the average amount delivered during the first 6 months of 1941. The order was amended February 7, 1942, to place cobalt in all forms under allocations, to prohibit its use in pigments after May 1, and to restrict nonessential uses further.

PRODUCTION

A considerable quantity of pyrites concentrates containing 1.3 percent cobalt was produced in 1941 by the Bethlehem Steel Co., Bethlehem, Pa. The cobalt is contained in the sulfides that accompany the

magnetite mined at Cornwall, Pa. The Eastern Magnesia Talc Co., Inc., Burlington, Vt., recovered 86 short tons of concentrates in 1941 as a byproduct of froth flotation of talc; 36 tons contained 1.97 percent cobalt and 17.19 percent nickel, and 50 tons contained 0.78 percent cobalt and 10.69 percent nickel. The higher-grade concentrate was sold. Otto F. Schwartz, manager of the Columbia mine near Goodsprings, Nev., sold about 2 tons of concentrate averaging 9.48 percent cobalt. Jonathan Gordon, Tombstone, Ariz., reported production of 10 tons of 12-percent cobalt concentrate at a property near Fort Thomas, Ariz.; a 20-ton mill was installed. The Sullivan Mining Co., Kellogg, Idaho, recovered 66 short tons of residue containing 7.19 percent cobalt at its electrolytic zinc plant in 1941, but none was shipped. Plans are under way to reopen the old Buckeye cobalt mine near Fredericktown, Mo. Sporadic attempts have been made to produce cobalt in the Southeastern Missouri district, where cobalt and nickel occur associated with lead, iron, and copper, but the complexity of the ore presents a problem in metallurgy. According to George F. O'Brien, Ironton, Mo., development and exploratory work is progressing on the high-silica, low-manganese ore deposits in Reynolds and Madison Counties, Mo.; these ores are reported to contain 0.5 to 4.8 percent cobalt oxide, and work is under way on a process for recovering the cobalt. Experimental work on electrowinning of cobalt from ores is described in Report of Investigations 3600.[1]

FOREIGN TRADE[2]

Although figures on imports in 1941 are available for publication for only the first 9 months of the year, the partial total is only about 17 percent less than the all-time record established in 1940. Of the partial 1941 imports, Belgian Congo supplied 80 percent in the form of residues (averaging 41 percent cobalt) and Canada 5 percent as ore (averaging 9 percent cobalt) and 14 percent as metal. Data on exports are not given by the United States Department of Commerce.

USES

An important use for cobalt is in the manufacture of high-speed cutting tools for operation at high speeds or at high temperatures. It also is employed in alloy steels for high-temperature dies, heavy-duty shears, and other implements requiring extreme toughness combined with great hardness at high temperatures. The largest single use of cobalt is in stellite or stellite-type alloys, which contain 45 to 55 percent cobalt, 30 to 35 percent chromium, and 12 to 17 percent tungsten; there are various modifications of this composition, but all contain high percentages of cobalt. A comparatively small quantity of cobalt is used in carbide-type alloys. A substantial quantity of cobalt is used in permanent magnets, which are employed in electric meters, relays, regulating devices, fractional horsepower motors and generators, switching appliances, and a variety of other uses. Cobalt is also employed in alloys where constant magnetic permeability at low magnetic forces is necessary. Comparatively small quantities of cobalt are used in electroplating and as a catalyst. Cobalt oxide is utilized in the ceramic industry; and cobalt salts are employed in the preparation of driers for use in paints, varnishes, and linoleums and as a catalyst.

WORLD PRODUCTION

Because cobalt-production data published by many of the producing countries are given in such indefinite figures and because those for certain countries are lacking, it is impossible to prepare an accurate statement of world output. Despite the fact that cobalt has been reported produced in about 14 countries, Belgian Congo, Burma, Canada, French Morocco, and Northern Rhodesia have in recent years supplied the bulk of the production, which increased from about 1,200 metric tons in 1929 to 4,500 to 5,000 tons in 1939.

Brazil.[3]—The Empresa Brasileira Mineracão Ltda. of São Paulo, a Japanese organization, was established by decree 4882 on November 16, 1939. The shares in the company were held by Brazilian-born citizens who were in the employ of the company and constitute the Board of Directors. The real owners, as well as the men in charge

[3] Wright, C. W., and Pardee, F G., The Nickel-Cobalt Deposit at São José do Tocantins, State of Goyaz, Brazil: Ms. Rept., June 4, 1941, pp. 15–16.

of operations at the mine, were Japanese. After several months of investigation the company signed a contract with the Empresa Commercial of Goyaz, S. A., on October 28, 1940, to obtain the privilege of mining cobalt ore over a period of 7 years and to pay for the ore extracted upon a basis of 50$000 a metric ton for ore with 3 percent cobalt, plus 10$000 for each additional 0.1 percent. Thus, ore containing 4.5 percent cobalt would bring 200$000 a ton, or $10 in United States currency. Under the contract, all operating expenses and construction and upkeep of roads from the mine at Anapolis were to be paid by the Empresa Brasileira Mineracão Ltda. During the first 5 months of 1941, cobalt ore produced totaled 141 tons. In the early part of 1941, a plant with trommels, sorting belts, and cleaning drums was being built which was expected to increase daily production capacity to about 10 tons. Mining operations were confined to the Jacuba II section, where the ferruginous capping of the serpentine was being excavated for its cobalt content. This area of capping, was about 500 meters long, 200 meters wide, and less than 1 meter to several meters thick (the average being about 1.5 meters). This capping is excavated by pick and shovel and transported in wheelbarrows to screens, where fines under ⅜-inch are screened out. The oversize material is sorted into medium-, high-, and low-grade piles. Only the high-grade ore was transported in automobile trucks to the washing plant below the Jacuba camp. Twenty-five men were employed at the mine, and about 50 tons of material were handled daily. At the washing plant, 2 kilometers from the mine, the ore was washed and sized in a trommel. Ore larger than 1 inch went to sorting tables where the higher-grade ore was separated, about 20 percent being discarded. Ore less than 1 inch went to a cleaning drum about 1 meter in diameter and 1 meter in length, into which the ore was dumped in batches, with an equal amount of quartz sand, and rolled for several minutes to remove the iron oxide coating on the surface of the small pieces. Loss of cobalt ore due to abrasion by this treatment was estimated at 5 to 10 percent. The final product contains 4 to 4.5 percent cobalt, which was shipped to Japan in bags holding 100 pounds.

Canada.—As a result of improved demand, activity in the Cobalt district, Ontario, increased. Over 50 properties are being worked for silver and cobalt.[4] The many small leasers in the Cobalt camp suffered a severe handicap when the plant of Temiskáming Testing Laboratories (Ontario Government sampling plant) was destroyed by fire in July 1941.[5] Leasers depended on the plant for the sampling valuation, and frequently the marketing of their ore.

Chile.—During November 1941, Chile shipped 525 metric tons of cobalt ore to Japan. The Compañiá Minera "La Cobaltera," which operates a cobalt deposit near Puerto del Huasco in the Province of Atacama, suspended operations temporarily to install a concentrating plant and make other necessary improvements; regular production is not expected to be resumed until the improvements are completed, probably in 1942. The Cobalt Minerals Corporation has been formed to exploit cobalt deposits in Chile.[6] Although the deposits, so far as known, are not particularly extensive, it is reported that up to 600 tons of concentrates averaging 10 to 12 percent cobalt could be produced annually.

MOLYBDENUM AND VANADIUM

By FREDERICK BETZ, JR., AND A. P. VAN SICLEN [1]

SUMMARY OUTLINE

MOLYBDENUM

SUMMARY

Domestic production of molybdenum reached a new peak in 1941, with a total of 40,162,000 pounds (contained molybdenum), or 17 percent above the previous peak of 34,313,000 pounds in 1940. Fragmentary data with respect to production elsewhere in the world indicate that Latin American countries continued to produce a few hundred tons of molybdenum. What transpired in most molybdenum-producing countries may only be surmised, but in general the record of molybdenum centers around developments in the United States.

As actual or threatened shortages of strategic metals employed in steel alloying developed, molybdenum became increasingly important in the defense program, and its use was regulated in a series of orders issued by the Office of Production Management.

In 1941, as in 1940, shipments of molybdenum concentrates from the United States to foreign countries represented about 19 percent of domestic production, compared with 67 percent in 1939. Most of the 7,673 short tons of molybdenum ore and concentrates exported (valued at $5,379,367) went to the United Kingdom and U. S. S. R.

As has been the case for a number of years, the Climax Molybdenum Co. was the world's leading producer of molybdenum, and in 1941 it supplied 69 percent of the domestic output. Molybdenite concentrates recovered as a byproduct of copper operations at Bingham, Utah, Santa Rita, N. Mex., and Miami, Ariz., have become an established source of supply and in 1941 represented 28 percent of the United States production of molybdenum.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Salient statistics of the molybdenum industry in the United States, 1939–41

	1939	1940	1941
Concentrates			
Production short tons	32,347	33,128	38,962
Molybdenum contained pounds	30,324,000	34,313,000	40,162,000
Shipments (including exports) short tons	31,479	24,300	36,894
Molybdenum contained			
Average percent	51.49	52.12	51.77
Total pounds	32,415,000	25,329,000	38,200,000
Value [1]	$22,157,000	$17,189,000	$25,883,000
Exports short tons	21,777	6,339	7,673
Molybdenum contained pounds	(2)	6,584,714	7,640,330
Value	$14,066,501	$4,904,000	$5,379,367
Imports for consumption (molybdenum contained):			
Pounds	26,347		4,300
Value	$32,327		$2,898

[2] Not recorded.

DEFENSE PROGRAM

Recognition of the possibilities of using molybdenum in place of tungsten is by no means recent. References cited by Gregg [2] indicate that early in the twentieth century a number of investigators were studying the properties of molybdenum as a steel-alloying element and its effective value in replacing tungsten for such use. Anticipating the possibility that imports of tungsten might be curtailed, several steps were taken by Federal defense agencies during 1941 to promote the use of molybdenum as a substitute material. The Advisory Committee on Metals and Minerals of the National Academy of Sciences submitted a report in April 1941 indicating that molybdenum high-speed steels can be substituted for tungsten steels "rather sweepingly if the necessity arises."

Molybdenum was one of 16 metals included in O. P. M. General Metals Order 1, issued May 1, 1941, to which inventory control was applied. The order provided that the metals affected might not be shipped to customers in quantities that would increase customers' inventories to unnecessary levels. The 16 metals were then placed on the Priorities Critical List. (General Metals Order 1 was extended to October 15, 1941, and subsequently revoked.)

On June 12, 1941, General Preference Order M-14 was issued, which provided that a customer for high-speed steel might not purchase the tungsten-type steel (containing more than 12.0 percent tungsten) if the molybdenum type (7.0 percent or less tungsten and more than 3.0 percent molybdenum) would serve as well. It provided further that during any 3-month period, beginning June 1, 1941, a customer for high-speed steel might purchase tungsten-type steel only to the extent that he bought molybdenum-type steel.

Early in December the foregoing order was amended to provide that 75 percent of all high-speed-steel orders accepted in any one quarter should be of the molybdenum type and not more than 25 percent of the tungsten type. The order was also extended to December 31, 1942.

As a result of the increased use of molybdenum in replacing tungsten in alloy steels, the War Production Board issued General Preference Order M-110 on March 18, 1942, providing for complete alloca-

[2] Gregg, J. L., The Alloys of Iron and Molybdenum. McGraw-Hill Book Co., Inc., New York, 1932, 507 pp.

tion of molybdenum in all forms, including scrap, until December 31, 1942. Provisions of the order were to become effective May 1, 1942.

PRICES

Engineering and Mining Journal quotations for 90 percent molybdenum concentrates remained constant at 45 cents per pound throughout the year. Ferromolybdenum containing 55 to 60 percent Mo was quoted at 95 cents per pound of Mo, f. o. b. shipping point, throughout the year; prices for calcium molybdate at 80 cents per pound of Mo contained and molybdenum metal (99 percent) at $2.60 to $3.00 per pound were also constant.

DOMESTIC PRODUCTION

The spectacular development of the molybdenum industry from the first year of World War I to the end of 1941 is shown in the following table.

Molybdenum in ore and concentrates shipped from mines in the United States, 1914–41

Year	Pounds	Value [1]	Year	Pounds	Value [1]
1914	1,297	$1,297	1928	3,329,214	$1,924,600
1915	181,769	114,866	1929	3,904,648	2,259,000
1916	206,740	205,000	1930	3,759,269	2,068,000
1917	350,200	495,350	1931	3,157,000	1,577,000
1918	861,637	1,253,700	1932	2,373,000	1,186,000

[1] Largely estimated by Bureau of Mines.

Arizona.—Among the smaller domestic producers of molybdenum is Mammoth-St. Anthony, Ltd., operating at Tiger, Pinal County. In addition to molybdenum, the values recovered are gold, silver, lead, and vanadium. Huttl [3] has recently summarized the operations, stating that: "The enterprise is essentially a low-grade gold mine, with a large daily tonnage and careful management as the principal requisites for making the ore bodies economically important." The molybdenum ore is wulfenite ($PbMoO_4$). Over-all recovery of molybdenum in the Mammoth-St. Anthony operation is 97 percent in the mill and 74 percent in the smelter. The smelter has a daily capacity of about 20 tons. The slag containing the molybdenum and vanadium values is treated further, yielding a Na_2MoO_4–$Na_2V_2O_4$ salt, which is shipped. The Miami Copper Co. continued to recover molybdenum as a byproduct of copper-mining operations at Miami, Gila County. A roaster converts the molybdenite concentrates to molybdic oxide.

California.—The United States Vanadium Corporation completed a new concentrating and chemical treatment plant near its tungsten

[3] Huttl, John B., Mammoth-St Anthony's Complex Operations Eng and Min. Jour, vol 142, No. 12, December 1941, pp. 42-45.

mine on Pine Creek near Bishop, Inyo County. The new plant, with an initial capacity of 1,300 tons of tungsten-molybdenum ore a day, replaced a 450-ton plant at the mine. Burwell [4] has described the milling process and metallurgical problems encountered in developing this operation. Molybdenum is one of the byproducts, which include also copper, silver, and gold. The molybdenum minerals in the ore are molybdenite, molybdite, and powellite.

Colorado.—In 1941, production by the Climax Molybdenum Co. increased nearly 22 percent to 27,751,273 pounds of elemental molybdenum. Except for the record high output attained in 1938, this production was the greatest since the company began mining in 1918. Production of molybdenum from the Climax deposit from 1918 to 1941 has been as follows:

Molybdenum (element) contained in concentrates produced from the Climax deposit in Colorado, 1918–41

The following excerpts from a recent article by Duggan [5] trace the history of this unique operation:

The mine and mill of the Climax Molybdenum Co. are at Climax, Colo., on Fremont Pass, directly on the Continental Divide, at an elevation of 11,400 feet.

The Climax ore-bearing rock is essentially an altered and highly silicified granite, fully half of the gangue being quartz. Molybdenite is the only mineral of economic consequence, and most of it is intimately associated with quartz in the form of fine veinlets and stringers. Other minerals are molybdite, pyrite, and chalcopyrite. While the molybdite may be readily extracted by hydrometallurgical methods, its content is too low to make such operations profitable. The pyrite content ranges from 2 to 5 percent and that of the chalcopyrite from 0.03 to 0.05 percent. There is not enough copper to make its recovery attractive, and one of the metallurgical problems is the elimination of it and the pyrite from the product.

On account of the close association of the molybdenite with the quartz and the necessity of eliminating the pyrite and chalcopyrite from the final product, fine grinding followed by flotation is the only feasible method of concentration.

Construction of the first milling unit was started in 1917, and it was operated during parts of 1918 and 1919.

In the post-war years, there was almost no demand for the product and production was at a standstill until 1924. The company's research campaign to develop the use of the metal began to show results in that year. From 1926 to 1932 production ranged from 500 to 1,200 tons per day. In 1931 an additional mill section was built, and production was gradually increased until in 1934 and 1935 about 3,000 to 4,000 tons was milled per day. This tonnage overtaxed the milling facilities, and as the demand for molybdenum was growing constantly, additional milling equipment was needed. In 1936 and 1937 another crushing plant, six additional mill sections, and the necessary auxiliary plants were constructed and brought into operation.

[5] Duggan, E. J., Climax Milling Practice: Am. Inst. Min. and Met. Eng., Tech. Paper 1456, Min. Technol., March 1942, 15 pp.

This plant was designed to mill 10,000 tons per day, but it was not long before 12,500 tons was being treated during periods of peak demands. During the summer of 1941, to meet defense needs, the mill has been required to treat 15,500 tons per day. This has been accomplished with little plant expansion and at no loss in recovery. To increase capacity still further, one more primary section is being built. This will bring capacity to 18,000 tons per day, which can be stretched to 20,000 tons at a small sacrifice in recovery.

The foregoing article also describes milling methods in considerable detail; additional information on mining methods, with special reference to blasting practice, was made available by Barker.[6]

New Mexico.—The Molybdenum Corporation of America continued to operate its mine and mill near Questa, Taos County. Ore of relatively high grade is mined, and the tonnage treated is comparatively small. The Nevada Consolidated Copper Corporation recovered molybdenite as a byproduct from its copper concentrate at the Chino property in Grant County.

Utah.—The only producer in Utah in 1941 was the Utah Copper Co. at Bingham. The molybdenite concentrate is obtained as a byproduct in the concentration of copper ores and in the re-treatment of molybdenum-bearing concentrates.

EXPORTS AND IMPORTS

Total exports of molybdenum ore and concentrates in 1941 were 15,345,251 pounds, containing 7,640,330 pounds of molybdenum, with a value of $5.379,367; this total represents a 16-percent increase over 1940 in molybdenum contained. Large increases were shown in shipments in 1941 to Canada, U. S. S. R., and United Kingdom. Exports of molybdenum to France, Italy, and Japan ceased. Chile entered the list of countries receiving molybdenum from the United States, whereas no exports to Brazil were recorded during 1941.

Molybdenum ore and concentrates exported from the United States, 1940–41, by countries

Country	1940			1941		
	Gross weight (pounds)	Molybdenum content (pounds)	Value	Gross weight (pounds)	Molybdenum content (pounds)	Value

Imports of molybdenum in molybdenum ore and concentrates in 1941 totaled 4,300 pounds; there were none in 1940. In 1939, 26,347 pounds were imported in ferromolybdenum, etc.

[6] Barker, Claude L., The World's Largest Molybdenum Mine: Mines Mag., vol. 31, No. 11, November 1941, pp. 558–564, 568.

Molybdenum ore and concentrates, ferromolybdenum, molybdenum metal and powder, calcium molybdate, and other compounds and alloys of molybdenum imported for consumption in the United States, 1937–41

Year	Molybdenum content (pounds)	Value	Year	Molybdenum content (pounds)	Value
1937	7,707	$13,491	1940		
1938	25	81	1941	4,300	$2,898
1939	26,347	32,327			

USES

Approximately 93 percent of the molybdenum consumed in the United States is employed in steel ingots and castings; 3 or 4 percent goes into iron castings; and the remainder is used in miscellaneous products, such as pigments and colors, welding rods, etc. Molybdenum is becoming of increasing interest as a substitute material for tungsten and other steel-alloying metals, of which domestic supplies are limited. Its chief field of usefulness in this capacity is to replace tungsten, as mentioned elsewhere in this chapter. However, the Advisory Committee on Metals and Minerals of the National Research Council has called attention to the value of molybdenum in relieving threatened shortages of vanadium, caused by substitution of the latter for nickel.[7]

A tabulation of 1,500 tool steels compiled by Lippert [8] includes more than 250 with molybdenum contents ranging from as little as 0.15 percent to the molybdenum high-speed steels, which may be as high as 9 percent Mo. Increased use of molybdenum-type high-speed steels has been facilitated by release of patents covering their production by several companies holding them.

For use in alloy steels, molybdenum may be added in the form of ferromolybdenum, calcium molybdate, and molybdenum oxide (roasted molybdenite). Common practice favors use of the oxide, and nearly half of the molybdenum employed in alloy steels enters in that form.

As was to be expected, compliance with O. P. M. orders substituting molybdenum-type high-speed steels for tungsten high-speed steels presented certain technical difficulties, which are being solved as rapidly as possible. Recommendations concerning the handling of molybdenum high-speed steels were made by a special committee of O. P. M.[9]

According to Edsall and Lloyd,[10] solution of a major problem—that of heat treating—may be achieved through use of the electrically heated salt bath. Procedure to be followed in salt-bath hardening

of molybdenum high-speed steels was also described in the report of a special committee of O. P. M. headed by A. F. Holden.[11]

Another O. P. M. committee report[12] presents details of surface protection of molybdenum high-speed steels through use of controlled-atmosphere furnaces.

A molybdenum stainless steel has been developed that is said to have great strength and freedom from chemical or electrical reaction and to be adapted to treatment of bone fractures. It may be used in the form of steel plates, screws, nails, and wire in surgery, and the manufacturer claims that it provides bone surgeons with a strong, durable metal that will not corrode in human tissues.[13]

British practice in use of molybdenum in "high-strength" iron was reviewed by A. McRae Smith,[14] who stated that "in correctly balanced proportions, added to a suitable base composition, nickel and molybdenum impart to cast iron the maximum tensile and transverse strengths and deflection so far achieved in any material which is a true gray cast iron."

Minor outlets for molybdenum include its use in pigments and colors, welding rods, and wire and for various chemical purposes. Such uses, however, represent specialized fields in which relatively few manufacturers participate. Applications for black molybdenum finishes are described by Young,[15] who mentions jewelry, instrument-gage dial, and decorative fields. Colors ranging from rainbow effects to black deposits may be obtained with coatings produced in a solution containing ammonium molybdate, sodium thiosulfate, and some ammonium hydroxide. Molybdenum black coatings may be applied to electroplated zinc and cadmium, die-cast zinc, die-cast aluminum, and rolled aluminum.

TECHNOLOGIC DEVELOPMENTS

A sample of wulfenite (lead molybdate) ore from Arizona was tested in the Ore-Dressing Section of the Metallurgical Division of the Bureau of Mines at Rolla, Mo., to determine whether molybdenum-bearing concentrates could be obtained by gravity-concentration methods avoiding formation of slime and attendant loss of value. The investigators concluded that careful stage-crushing is essential to avoid excessive sliming and that with efficient hydraulic classification and table concentration good recovery of the valuable mineral should result.[16]

WORLD PRODUCTION

The production of molybdenum outside the United States is very small. Figures covering such output in 1941 are available only for Chile, Mexico, and Peru; except for Norway, these countries appear to be the only significant foreign sources of supply.

[1] In addition to the countries listed, molybdenum ore is also produced in Burma, China, Chosen, and Japan, but data on production are not available.
[2] Data not available.

In Canada, the Moss mine, in the Quyon district of Quebec, controlled by the Quyon Molybdenite Co., was active during the latter part of 1941. Operation of the mine was undertaken during the first World War by The Canadian Wood Molybdenite Co.; subsequently the property changed hands several times and was worked intermittently. The present management took charge in 1938 and has built a mill and smelter. Output was reported to be at the rate of about 6 tons of 90-percent concentrates a week, and ore reserves were estimated at 30,000 tons averaging 0.5 percent MoS_2. Production of molybdenum in Chile, where molybdenite concentrates are recovered from copper operations of the Braden Copper Co. at Sewell, amounted to 229 metric tons (Mo content) in 1941. In January 1942 the Government of Chile entered into an agreement granting the United States exclusive buying rights on all molybdenum produced in Chile for 18 months. Peru Molibdeno, S. A., principal producer in Peru, continued to operate its mine near Ricran, in Juaja, Department of Junin. With the expiration of contracts for shipments of molybdenum to Japan, all future exports were destined for England. Discovery of a molybdenum deposit was reported in Salvador [17] 8 km. east of the village of Teputla, Department of Chalatenango, and 40 km. from La Toma, the nearest railway point. Prospecting revealed a 4- to 5-foot vein in a 30-foot shaft; ore samples were reported to contain 8.5 to 19 percent MoS_2.

VANADIUM

SUMMARY

In 1941 the United States became the world's leading producer of vanadium, displacing Peru which held that position from 1938 to 1940. Domestic production, in terms of vanadium contained in ore distributed to mills and domestic consumers, amounted to 2,393,478 pounds (1,086 metric tons) in 1941 compared with 2,162,916 pounds (981 metric tons) (revised figures) in 1940. Peru's production decreased from 1,214 metric tons (vanadium contained) in 1940 to 1,017 tons in 1941. A marked decline was noted in the vanadium output of South-West Africa. No statistics are available concerning production in Northern Rhodesia. The demand for vanadium in the United States has increased steadily. Apparent consumption in 1940 was estimated at 3,000,000 pounds by the Office of Production Management, which on August 16, 1941, stated that "The current rate of production would indicate that 3,750,000 pounds in finished form will be made available in 1941 as against an estimated need of 5,900,000 pounds. Requirements for 1942 are expected to reach 7,150,000." Vanadium was placed under full priority control on August 14. On December 20, a complete allocation system was established for vanadium by the O. P. M.

The only countries known to have important vanadium-ore deposits are the United States, Peru, South-West Africa, and Northern Rhodesia. Vanadium has been and is now being obtained by some countries from other materials, including petroleum, bauxite, phosphate rock, and titaniferous magnetites. The ever-increasing demand for vanadium directs attention to all possible vanadium resources, as well as to efforts to extend known deposits.

In the United States the principal ores are roscoelite and carnotite in sandstones, disseminated or in spots, bunches, lenses, and seams. These desposits, representing a distinct type, are found in southwestern Colorado and in southeastern Utah. Application of geophysical methods in this region to locate further concentrations of ore was discussed by Kelly.[18]

[18] Kelly, S. F., Geological Studies of Vanadium-Uranium Deposits by Geophysical Exploration Methods: Min. Cong. Jour., vol. 27, No. 8, August 1941, pp. 27-35.

Interest was shown in lead vanadate deposits in the western United States. Under normal conditions, these deposits do not have commercial value, but the Metals Reserve Co. reported that arrangements had been completed for rapid development of several such properties to augment the domestic vanadium supply.

The Bureau of Mines investigated the metallurgical treatment of vanadium ores (including carnotite, cuprodescloizite, descloizite, and vanadinite) from Colorado, Nevada, and Arizona.[19]

Vanadium was recovered from flue dust gathered from the boilers of ships burning Venezuelan fuel oil. The dust is said to contain 20 to 40 percent V_2O_5. Lately, Argentine petroleum and asphaltite have been examined for their vanadium content. The investigators, Fester, Cruellas, and Baron,[20] state that the oils contain vanadium in quantities too small to be recovered economically. Referring to the asphaltites, these authors find that, whereas Peruvian bituminous material contains 0.5 to 1.5 percent V_2O_5, the samples from the Provinces of Mendoza and Neuquén, Argentina, contained only 0.1 to 0.2 percent. In 8 of 24 analyses given the content was below 0.1 percent.

The presence of vanadium in titaniferous magnetites is well-known. Actual recovery from converter slag has been carried on in Germany, where, it is believed, this source meets the vanadium requirements of that country. Research on recovery of vanadium from slags is reported from U. S. S. R. In a recent study of the titaniferous magnetites of the Laramie Range, Wyoming, Diemer[21] gives six new analyses in which the V_2O_3 content ranges from 0.32 to 0.53 percent. Frankel and Grainger[22] report 1.08 percent V_2O_3 in a sample of titaniferous iron ore from the Bushveld Complex of South Africa and note that the content of all samples examined thus far rarely exceeds 1 percent V_2O_3. They concur in the results of investigations in India by Dunn and Dey[23] who found that the vanadium is present in coulsonite, a mineral possibly of the composition $(FeV)_2O_3$. Frankel and Grainger believe that the intimate association of the minerals in the Bushveld ore, presumably a typical titaniferous iron ore, would militate against successful concentration of any of its constituents by physical methods.

DEFENSE PROGRAM

Vanadium was among the metals included in the inventory control provided by General Metals Order 1, May 1, 1941, issued by the Office of Production Management. It was removed from this order on August 14 and placed under full priority control, effective September 1. The new regulation (Order M–23) gave high ratings to all defense orders for vanadium and required their acceptance in preference to nondefense orders; a purchaser of vanadium was required to file a statement of the intended uses not later than the twenty-fifth of the month preceding that specified for delivery; deliveries were restricted to an amount not in excess of that necessary to fill a given manufacturer's orders on the basis of his current method and rate of production. On December 20, General Preference Order M–23–a replaced the previous priority-control order. It "provides for monthly requests for vanadium allotments and authorizes the Director of Priorities to make monthly allocations without regard to previous

preference ratings." Consumers receiving less than 50 pounds a month are not obliged to file reports. The order, as originally announced, was to be effective until June 30, 1942.

Vanadium was among 13 materials listed in General Imports Order M-63, which took effect December 28, 1941. The order provided that "unless otherwise authorized by O. P. M., all future contracts for imports of these materials will be handled by the Metals Reserve Co., R. F. C. subsidiary, or other governmental agency. No private person or concern can make arrangements for imports, except that in certain cases, such as imports for processing and immediate re-export, the Director of Priorities may grant specific exceptions to the Order." The Metals Reserve Co. was stated to be planning to work through established brokers and dealers.

PRICES

Engineering and Mining Journal Metal and Mineral Markets quoted a nominal price of 27½ cents per pound of V_2O_5 contained for vanadium ore throughout 1941. Ferrovanadium was quoted at \$2.70 to \$2.90 per pound of V contained, and the price of vanadium pentoxide (technical grade, approximately 88 to 92 percent V_2O_5) quoted by Daily Metal Trade was \$1.10 per pound of V_2O_5 contained.

DOMESTIC PRODUCTION

Arizona.—Vanadium is recovered from complex ores at Tiger Pinal County, by Mammoth-St. Anthony, Ltd., a low-grade gold mine that yields values in silver, lead, molybdenum, and vanadium, in addition to gold. The vanadium-ore minerals are vanadinite and descloizite. The vanadium and molybdenum are shipped as a Na_2MoO_4–$Na_2V_2O_4$ salt. Operations have been described by Huttl.[24]

Colorado and Utah.—The principal vanadium-ore district in the United States lies in southwestern Colorado and southeastern Utah. The vanadium resources are large, but the individual ore bodies are widely scattered and generally small. Facilities for treating the ores are being expanded in this region, and mining is being carried on at increased rates to meet the present demand for vanadium. Production in Colorado and Utah in 1941, in terms of vanadium contained in vanadium and uranium (carnotite) ores shipped from mines to treatment plants and domestic consumers, amounted to 2,287,718 pounds.

The United States Vanadium Corporation operated its 240-ton mill and a plant to treat tailings at Uravan, Colo. The company also worked on the construction of a new mill at Rifle, Colo., where vanadium operations were carried on from 1925 to 1932. The new plant has a capacity of 200 tons; the first unit—a 100-ton roaster—went into operation in February and the second in April 1942.

The Vanadium Corporation of America treated ore at its Naturita (Colo.) plant during 1941; the mill, reopened in 1940, has a capacity of about 50 tons and handles ore from company property in Montrose and San Miguel Counties, Colo., as well as custom ore. Through a lease agreement with the Defense Plant Corporation, the company will erect a 120-ton plant at Monticello, Utah. The cost of the plant—\$875,000—is being provided by the Defense Plant Corporation, which retains title to the facilities. Operation is scheduled to begin about

[24] Huttl, John B., Mammoth-St. Anthony's Complex Operations Eng. and Min. Jour., vol. 142, No. 12, December 1941, pp. 42–45.

July 1, 1942. In preparation for this new activity, the company maintained during 1941 an ore sampler at Monticello, where ore was purchased and stock-piled.

North Continent Mines, Inc., continued to operate its mill at Slick Rock near Cedar, San Miguel County, Colo. At Gateway, Mesa County, Colo., the Nisley & Wilson Vanadium Mill produced vanadium oxide from custom ores. Gateway Alloys, Inc., formerly treating ore at Gateway, restricted its activity to mining. The Blanding Mines Co. produced ore and oxide from its mine and mill at Blanding, San Juan County, Utah.

Idaho.—The Anaconda Copper Mining Co. recovered vanadium as a byproduct in the treatment of phosphates for fertilizer. The phosphate rock is mined at Conda, Idaho, and treated in reduction works at Anaconda, Mont.

FOREIGN TRADE

Imports of vanadium ores in 1941, virtually all from Peru, totaled 12,323 short tons with a vanadium content of 2,138,608 pounds. Data on exports of vanadium ore and concentrates were not available before 1941. The total exports during 1941 were 28 short tons containing 25,462 pounds of vanadium; details by countries of destination are shown in the following table.

Vanadium ore and concentrates exported from the United States in 1941, by countries

Country	Gross weight (pounds)	Vanadium content (pounds)	Value
Canada	37,150	17,578	$35,603
Japan	7,470	3,552	9,879
Netherlands Indies	629	256	531
United Kingdom	10,422	4,076	17,200
	55,671	25,462	63,213

USES

The principal use of vanadium is in the manufacture of high-speed and low-alloy tool steels and high-strength cast iron and steel forgings. The present demand for vanadium is reflected in the increased use of vanadium-bearing steels, which have been substituted for steels containing nickel and tungsten.

The role of vanadium in forging spring and cast steels has been discussed by Dawe,[25] who states that—

Vanadium as an alloying element in steel has, in recent years, experienced a rapidly increasing number and range of applications. Small percentages have been found to contribute a variety of valuable properties—from toughness, uniformity, and carburizing qualities in the smallest forgings and springs to higher impact resistance, reduction of internal defects, and increased strength in the largest forgings and castings. In addition, a number of other effects generally accompanies the presence of a small amount of vanadium. These include improved machinability, simpler heat treatment, reduced distortion, exceptional weldability, increased wear resistance, better control and uniformity of hardness penetration and gradient, smoother finish, and reduced flaking or spalling of carburized surfaces.

[25] Dawe, C. N., How Vanadium Influences Design Materials. Machine Design, vol 13, No. 10, October 1941, pp. 49–53, 110, 112.

Of interest at this time is the use of chrome-vanadium steels in making propeller hubs, gears, and welded propeller blades for aircraft. Light armor plate for planes and tanks is also made of vanadium steels.

In minor amounts, vanadium is utilized in the ceramic, glass, color, and nonferrous industries and as a catalyst in the manufacture of sulfuric acid.

Vanadium is made available to the steel industry in the form of ferrovanadium, which contains 35 to 40 percent of the element. It is also prepared for commercial use as vanadium oxide and ammonium metavanadate. Fused oxide is used to a minor degree in basic electric-furnace steels, but, in general, the oxide is produced for use in the minor applications mentioned above.

WORLD PRODUCTION

World output of vanadium in ore and concentrates in 1941 was similar in volume to that in 1940. The United States increased its production by 11 percent and assumed the leading position, displacing Peru which ranked second. The Minasragra property of the Vanadium Corporation of America, on the east side of the main Cordillera of the Andes at an elevation of 15,472 feet, produces most of Peru's vanadium output.[26] Part of the ore is treated at a concentrator near the mine. The concentrates average about 25 percent V_2O_5. Sorted ores are also shipped, and in the last 5 years the V_2O_5 content of these ores exported has ranged from about 7 to 15 percent. Vanadium-bearing asphaltites, chiefly in deposits of the Compania Minera Santa Clara y Llacsacocha at Yaulí, Department of Junin, are mined on a small scale.[27] The vanadium is concentrated in the ashes, which are obtained by burning the asphaltite. The company was preparing to mine vanadiferous coal for its vanadium content.

Production of vanadium in South-West Africa in 1941 came entirely from the Abenab and Baltika mines of the Southwest Africa Co., Ltd. Mottramite and descloizite, the vanadium-ore minerals, are found in clay pockets in dolomite. The concentrates average 19.75 percent V_2O_5. The Otavi Minen und Eisenbahn Gesellschaft of Tsumeb, which formerly supplied about half the output of the country, suspended operations in September 1940. The Union of South Africa Government was said to be planning to operate the Otavi company mines.

In U. S. S. R., plans were announced for exploiting titaniferous iron deposits (from which vanadium was also to be recovered) near Lake Onega in the Soviet Karelian-Finnish Republic. A plant was to be built at Pudozhgora to produce high-grade pig iron and ferrovanadium.

It is assumed that Germany and Italy continued to obtain vanadium from the same sources that were known in 1940. Vanadium G. m. b. H., a national cartel, was then reported to be responsible for furnishing the German requirements. Converter slag is the source of the vanadium. Italy recovers vanadium from naphtha soot collected from smokestacks of ships and industrial plants.

TUNGSTEN

By H. W. Davis

SUMMARY OUTLINE

SUMMARY

Consumption of tungsten concentrates in the United States reached an all-time high in 1941; as a consequence, both imports and domestic production established new records. Shipments of tungsten concentrates and high-grade sorted ore from domestic mines were 6,567 short tons (60 percent WO_3 basis), an increase of 23 percent over 1940 and 7 percent greater than in the previous record year 1917. Production in California, Idaho, and Nevada gained substantially in 1941; and the Yellow Pine mine in Idaho made its initial output and shipments in that year. Many new mills were completed during the year; especially noteworthy was the 1,300-ton-daily-capacity concentrating and chemical plant near Bishop, Calif., which began operating in the latter part of 1941. Additions to capacity were made at many existing mills.

Receipts of imported ore and concentrates during 1941 were 13,820 short tons (60 percent WO_3 basis), of which China supplied 68 percent and Latin American countries 25 percent.

Salient statistics of tungsten ore and concentrates in the United States, 1940–41

Stocks in bonded warehouses, Dec. 31	4,615	3,956,825	6,300	5,740,789

[1] Figures not available.

The Government program to buy tungsten ore for stock-piling and for resale to industry made substantial progress in 1941. Release to industry of part of the Government-held stock pile relieved a temporary stringency in the spot supply in the early part of 1941, which

developed as a result of the closing of the Burma Road from July 18 to October 17, 1940, cutting off tungsten supplies ordinarily supplied by China. The Metals Reserve Co. entered into a contract with Bolivian producers, guaranteed by the Bolivian Government, to purchase their entire production for 3 years at $21 per short-ton unit. An arrangement was also completed with the Argentine Government and producers to purchase up to 3,000 tons of tungsten concentrates for 3 years at $21 per short-ton unit. An agreement was also made to buy, at the market price at the time of purchase, any surplus Mexican tungsten not sold to private industry in the Western Hemisphere. Contracts have been made with three of the largest domestic producers of tungsten to permit substantial increases in output, and similar contracts are being arranged with numerous other producers. A re-treatment plant will be erected in Utah in 1942 to utilize large tonnages of low-grade concentrates, much of which has hitherto not been recovered. Arrangements are also being made for direct purchase of output from small producers. Under the stimulation of a price of $24 per short-ton unit and with the anticipated addition to output from re-treatment of low-grade concentrates, it is expected that domestic production will increase substantially by the end of 1942.

GOVERNMENT EXPLORATION

The Bureau of Mines continued its search for ore deposits of strategic metals, as authorized under section 7 of the Strategic Materials Act. Productive operation in the Yellow Pine district, Idaho, was begun in August over the deposit revealed in the course of diamond drilling by the Bureau of Mines in cooperation with the Geological Survey. This deposit appears to be one of the few outstanding new discoveries of tungsten ore in the United States since 1900. A large number of preliminary examinations of tungsten deposits were completed by the Strategic Minerals Examination Section of the Bureau's Mining Division. Trenching and diamond drilling were completed at Mill City, Nev.; near Bishop, Calif.; and in the vicinity of Shoshone, Nev., and the Huachuca Mountains, Ariz. Although no other large ore bodies were discovered, some ore was found in each instance, which enabled the operating companies either to increase or maintain production at properties where depletion of ore reserves would otherwise have forced reduction of output. At the Ima mine in Lemhi County, Idaho, important new discoveries were made by trenching and diamond drilling; their significance will be determined by further diamond drilling now in progress. It now appears that the new discoveries will bring about a considerable increase in the production rate.

As part of its program of investigation of strategic mineral deposits, the Geological Survey published reports describing tungsten deposits in the Sierra Nevada near Bishop, Calif., and in the Blue Wing district, Lemhi County, Idaho. The tungsten deposits in Mohave County, Ariz., including those in the Boriana mine, were mapped. Detailed mapping of the Tempiute district, Lincoln County, Nev., the tungsten deposits in Beaver County, Utah, and the Deer Park district, Stevens County, Wash., was undertaken. In California the tungsten deposits in the Darwin district, Inyo County, and the Greenhorn Mountain region in Kern and Tulare Counties were examined in considerable detail. In the Nederland district, Boulder County, Colo., the Yellow

Pine district, Valley County, Idaho, and the Seven Devils district, Adams County, Idaho, earlier examinations were continued or extended. A number of smaller districts were visited briefly.

PRICES

Quotations on tungsten ore and concentrates were relatively stable throughout 1941; imported and domestic ores fluctuated only \$2 and \$4 per unit, respectively. However, whereas the price trend of imported ore was downward, that of domestic ore was the reverse. Chinese ore was quoted in the Engineering and Mining Journal at \$26 per short-ton unit of WO_3, duty paid, at the beginning of 1941, was lowered to about \$24 in late January, advanced to \$24.50 in August, but again was reduced to \$24 in late October. Bolivian and Portuguese ores were quoted within the same range as Chinese ore. Domestic scheelite, in carlots, delivered, was quoted at \$23 to \$25 per short-ton unit during the first 9 months of 1941, at \$24 to \$27 in October, and at \$26 to \$27 during the remaining 2 months. The average price for the 1941 shipments, as reported to the Bureau of Mines, was \$23.41 per short-ton unit of WO_3.

DOMESTIC PRODUCTION

Stimulated by greater defense activities, production of tungsten concentrates and high-grade sorted ore in the United States increased 32 percent over 1940 to an all-time high of 6,746 short tons (reduced to an equivalent of 60 percent WO_3) in 1941. Production was obtained from a rather large number of widely scattered operations in Alaska, Arizona, California, Colorado, Idaho, Missouri, Montana, Nevada, New Mexico, South Dakota, Utah, and Washington. California, which displaced Nevada as the principal producing State in 1940, maintained its rank in 1941. Idaho attained the rank of third-largest producing State in 1941, as a result of production at the Yellow Pine mine, where the presence of tungsten was discovered in the spring of 1941.

Tungsten ore and concentrates produced and shipped in the United States, 1940–41, by States

State	Produced				Shipped from mines			
	1940		1941		1940		1941

Tungsten ore and concentrates shipped from mines in the United States, 1937–41

Year	Quantity		Reported value f. o. b. mines		
	Ore and concentrates, 60 percent WO_3 (short tons)	Tungsten content (pounds)	Total	Average per unit of WO_3	Average per pound of tungsten
1937	3,500	3,331,020	$4,094,000	$19.50	$1.23
1938	3,044	2,897,036	3,161,498	17.31	1.09
1939	4,287	4,080,024	4,402,182	17.11	1.08
1940	5,319	5,062,199	6,576,318	20.61	1.30
1941	6,567	6,249,945	9,223,726	23.41	1.48

Alaska.—At the Riverside mine near Hyder, 30 short tons of tungsten concentrates averaging about 53 percent WO_3 were produced (but not shipped) in 1941. About 700 feet of drifting, raising, and crosscutting from old workings were done during 1940 and 1941. According to J. H. Scott, owner and operator of the mine, metallurgical difficulties in the mill were numerous but are believed to have been solved. It is planned to install considerable additional equipment in the mill in 1942.

Arizona.—Shipments of tungsten concentrates from Arizona operations totaled 246 short tons averaging 67.49 percent WO_3 in 1941 compared with 302 tons averaging 69.33 percent WO_3 in 1940. The output comprised scheelite, wolframite, huebnerite, and ferberite. By far the largest output came from the Boriana mine near Yucca, Mohave County, where wolframite and scheelite concentrates averaging about 70 percent WO_3 were recovered from milling a 1.35-percent WO_3 ore. The mining and milling operations at the Boriana mine have been described in the Mining World.[1] The remainder of the output, which was produced at a number of widely scattered operations, came chiefly from the Tungsten Reef mines in Cochise County; the Gold Crown, Chloriding, and Diff claims and the Williams mine in Mohave County; and the Morning Star claim in Pinal County. At the Williams mine, where the Continental Mining Corporation did extensive development and installed mining and milling equipment and a power plant, operations were discontinued because of unsatisfactory results, mainly high operating costs. The tungsten deposits of Arizona have been described recently by Wilson.[2]

California.—California maintained its rank as the principal tungsten-producing State in 1941. Shipments of tungsten concentrates (virtually all scheelite) from California totaled 2,629 short tons averaging 59.42 percent WO_3 in 1941 compared with 2,076 tons averaging 59.83 percent WO_3 in 1940. Although tungsten concentrates were shipped from a large number of widely scattered operations, four producers—Atolia Mining Co. (in San Bernardino County) and United States Vanadium Corporation, Tungstar Corporation, and West Coast Tungsten Co. (all in Inyo County)—accounted for 2,263 tons, or 86 percent of the State total. The bulk of the remainder was shipped from the Black Rock mine in Mono County; Schober, Tung-

sten City, and Tungsten Blue mines in Inyo County; Woody, Tungsten Chief, and Sierra Tungsten mines in Kern County; Tungstore mine in Tulare County; and Garnet Dike mine in Fresno County.

Production of tungsten concentrates in California was 2,747 short tons averaging 59 percent WO_3 in 1941 compared with 1,935 tons averaging 60 percent WO_3 in 1940. Of the 1941 total, Inyo County supplied 65.7 percent, San Bernardino 24.8 percent, Mono 3.3 percent, Kern 2.6 percent, Tulare 1.5 percent, Fresno 1.3 percent, and Madera and undistributed 0.8 percent. The largest producer in California during 1941 was the United States Vanadium Corporation, which operated the Pine Creek mine near Bishop and, in addition, milled ore and tailings from other properties in California and Nevada. The concentrates recovered from milling ore and tailings from Nevada have been credited to that State in the statistics. The new concentrating and chemical treatment plant of the company was completed and put into operation the latter part of 1941. The daily capacity of the plant is 1,300 tons of tungsten-molybdenum ore. The process that has been developed to treat the complex Pine Creek ore is the result of 4 years of research and development. The new plant will replace the present 450-ton plant at the mine portal, at an elevation of 10,700 feet, and is situated at the junction of Pine and Morgan Creeks, 2 miles distant and 3,000 feet lower than the present mill. The original chemical plant first used in conjunction with the upper mill is being used as a custom plant to treat low-grade flotation concentrates from various mines. Residues as low as 2.75 percent WO_3 are being successfully treated in this plant, and the operator has been cooperating with other mills to make available the process developed at Pine Creek to produce additional tungsten to meet demands of the war program. The new concentrating and chemical treatment plant has been described by Burwell.[3]

A recent report[4] describes the tungsten deposits adjacent to Pine Creek and near the crest of the Sierra Nevada. It also includes brief summary descriptions of other prospects in extensions of the same narrow belt and of mines and prospects southwest of Bishop.

The mining and milling of tungsten at the Tungstar mine have been described by Lenhart[5] and Hamilton.[6]

The tungsten mines and deposits of California have been described by Partridge.[7]

Colorado.—Production of tungsten concentrates in Colorado was 810 short tons averaging 48 percent WO_3 in 1941, or virtually the same as in 1940. Shipments, however, declined slightly to 787 tons averaging 48 percent WO_3 in 1941 from 849 tons averaging 49 percent WO_3 in 1940. Virtually all the output was ferberite from Boulder County, the greater part of which came from operations of the Wolf Tongue Mining Co. and the Vanadium Corporation of America. A comparatively small quantity of huebnerite was produced in San Juan County in 1941.

[7] Partridge, J. F., Jr., Tungsten Resources of California: California Jour. Mines and Geol., vol. 37, No. 2, April 1941, pp. 225–326.

Idaho.—Production of tungsten concentrates in Idaho was 1,291 short tons averaging 30.81 percent WO_3 in 1941 compared with 224 tons averaging 64.84 percent WO_3 in 1940. Shipments were 1,269 tons averaging 31.03 percent WO_3 in 1941 compared with 240 tons averaging 65 percent in 1940.

The Ima mine in the Blue Wing district, Lemhi County, was inactive because of labor difficulties from August 1 to October 27, 1941. The mine power plant was destroyed by fire in January 1941. Chiefly as a consequence of these interruptions, production of huebnerite concentrates at the Ima mine declined to 180 tons in 1941 from 224 tons in 1940; the concentrates average about 65 percent WO_3.

At the Miller property, also in the Blue Wing district, the General Electric Co. has undertaken an extensive development program involving 3,000 to 4,000 feet of diamond drilling, trenching with a caterpillar tractor on some bedding veins, and a crosscut drift that has progressed nearly 2,000 feet. Not enough ore has been uncovered, however, to justify any milling operations.

The geology, ore deposits, and mines and prospects in the Blue Wing district, Lemhi County, have been described by Callaghan and Lemmon.[8]

The chief producing mine in Idaho is the Yellow Pine near Stibnite in Valley County, where tungsten production was begun in August 1941; during the remainder of 1941, 14,498 short tons of ore averaging 2.4 percent WO_3 were produced and treated, yielding 1,111 short tons of concentrates averaging 25.45 percent WO_3. The presence of tungsten at the Yellow Pine mine was discovered jointly by engineers of the Bureau of Mines and geologists of the Geological Survey in the spring of 1941. The Yellow Pine mine has been described in considerable detail by Bradley.[9]

Missouri.—A small quantity (3 short tons averaging 55.07 percent WO_3) of huebnerite was shipped from the Silver mine near Fredericktown, Madison County, in 1941. In 1940 shipments were 12 short tons averaging 65.13 percent WO_3.

Montana.—Production of scheelite concentrates in Montana was 8 short tons averaging 51.88 percent WO_3 in 1941 compared with 42 tons averaging 70.62 percent WO_3 in 1940. Of the 1941 total, 7 tons averaging 56.56 percent WO_3 were produced as a byproduct of gold at the Jardine mine in Park County, and 1 ton averaging 48.5 percent WO_3 came from the New Deal Placer property near Philipsburg, Granite County.

Nevada.—Nevada was the second-largest tungsten-producing State in 1941. Production and shipments of concentrates (reduced to an equivalent of 60 percent WO_3) were 2,316 and 2,289 short tons, respectively, in 1941 compared with 1,788 and 1,796 tons, respectively, in 1940. The greater part of the production was scheelite concentrates from operations of the Nevada-Massachusetts Co. and affiliated companies, which operate mills at Mill City, Golconda, and Oreana. The Nevada-Massachusetts Co. completed and put into production at Mill City a flotation plant to treat tailings from previous milling operations and the Golconda Syndicate at Golconda a chemi-

[8] Callaghan, Eugene, and Lemmon, D. M., Tungsten Resources of the Blue Wing District, Lemhi County, Idaho: Geol. Survey Bull. 931-A, 1941, pp. 1-21.
[9] Bradley, J. D., The Yellow Pine Mine—A Gold, Silver, Antimony, and Tungsten Producer in Central Idaho: Min. Cong. Jour., vol. 27, No. 9, September 1941, pp. 16-21.

cal plant to treat tungsten-bearing psilomelane. Smaller but important producers in 1941 were Nevada Scheelite, Inc., operating the Leonard mine in Mineral County; Tungsten Metals Corporation, operating the Scheelite Chief, Oriole, Everitt, and Silver Bell mines in White Pine County; and Lincoln Mines, Inc., operating the Tem-Piute mine in Lincoln County. At the Leonard mine the shaft was extended 150 feet, a station was cut on the 200-foot level, and 400 feet of drifting were done. Of the other smaller producing mines in 1941, the largest were the Tungsten Minerals, Hill Top, and Cherry Creek in White Pine County; Ajax and Gun Metal in Mineral County; Contact Group in Pershing County; Comet in Lincoln County; and Star in Elko County.

New Mexico.—Small quantities (50 units) of tungsten concentrates were produced at two localities in New Mexico in 1941—near Gage, Luna County, and White Oaks, Lincoln County.

South Dakota.—A small quantity of ore containing ferberite and scheelite was produced at the Mineral Ridge property near Hill City, Pennington County.

Utah.—Shipments from Utah were 44 short tons of scheelite averaging about 41 percent WO_3 in 1941 compared with 14 tons averaging 59.43 percent WO_3 in 1940. Although production came from operations in Beaver, Box Elder, Juab, Millard, and Tooele Counties, about three-fourths was from the Estelle mine in Tooele County and the Lone Pine mine in Box Elder. Mills were installed in Juab County near Delta by the Apex Tungsten Mining & Milling Co.; near Lucin, Box Elder County, by Massae Tungsten Mining Corporation; and near Milford, Beaver County, by the Prosper Mining Co. The tungsten ore body at the Prosper Mining Co. was discovered in October 1940, and in January 1941 part of it was leased to the Nevada-Massachusetts Co., which did considerable development work. In December 1941 the entire ore body and mill were leased to the Nevada-Massachusetts Co., which plans to remodel and greatly enlarge the mill. According to an announcement (March 26, 1942) of the Metals Reserve Co., "a re-treatment plant will be erected in Utah which will permit the utilization of large tonnages of low-grade concentrates, much of which has hitherto not been recovered. Arrangements are being made for direct purchase of production from small producers."

Washington.—Shipments of tungsten concentrates from Washington were 121 short tons averaging 33.91 percent WO_3 in 1941 compared with 92 tons averaging 48.68 percent WO_3 in 1940. The bulk of the production came from the Germania mine near Fruitland, Stevens County, where the General Electric Co. worked over surface float and tailings to recover 32 short tons of wolframite concentrates averaging 65 percent WO_3 and 75 tons of wolframite jig concentrates averaging 14 percent WO_3; no new development was undertaken at the property during 1941. Comparatively small quantities of wolframite concentrates were produced by James Keeth and the Industrial Tungsten Corporation from properties near Fruitland, Stevens County.

FOREIGN TRADE [10]

Domestic supplies of tungsten are inadequate for requirements, and the United States imports both tungsten concentrates and products,

[10] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

chiefly the former. Receipts of imported ore and concentrates (tungsten content) during 1941 totaled 13,152,716 pounds—a new record. Bolivia and China supplied 18 and 68 percent, respectively, of the 1941 total.

Imports for consumption amounted to 11,522,190 pounds (tungsten content) during 1941, and Bolivia and China supplied 25 and 57 percent, respectively. In addition, 27,558 pounds of tungsten in concentrates were imported from Bolivia for smelting, refining, and export during 1941. Material brought in for smelting, refining, and export is free of duty. There is no record of any exports of tungsten ore and concentrates from the United States.

Tungsten ore and concentrates imported into the United States in 1941, by countries

[1] Comprises ore and concentrates received in the United States; part went into consumption during year and remainder entered bonded warehouses.
[2] Comprises ore and concentrates withdrawn from bonded warehouses during year (irrespective of time of importation) and receipts during year for consumption
[3] In addition, following quantities were imported for smelting, refining, and export—1941: 48,196 pounds containing 27,558 pounds of tungsten and valued at $21,1[illegible] , 1940 2,546,166 pounds containing 1,348,495 pounds of tungsten and valued at $1,023,426.

Imports of tungsten metal were 36,793 pounds (tungsten content) valued at $48,307 in 1941; all came from the United Kingdom. No tungsten carbide, tungstic acid and other compounds of tungsten, or combination containing tungsten or tungsten carbide was imported in 1941.

Exports of tungsten metal, wire, shapes, and alloys other than ferrotungsten (for which export data are not available) were 195,762 pounds in 1941 compared with 237,940 pounds in 1940.

USES

Of the tungsten ore and concentrates consumed in the United States during 1941, about 75 percent was converted to ferrotungsten and metallic tungsten, 20 percent was added directly to furnaces in the manufacture of alloy steel, and 5 percent was used in various tungsten chemicals.

The chief use of tungsten, according to quantity, is in the manufacture of cutting tools, the majority of which are made of high-speed steel containing about 18 percent tungsten, 4 percent chromium, and 1 percent vanadium—commonly known as "18–4–1." Smaller quantities of tungsten are used in numerous other types of high-speed steels. Other important uses of tungsten are in stellite and tungsten carbide cutting tools, magnet steels, austenitic valve steels and valve seats, armor-piercing projectiles, and erosion-resisting gun liners. Minor amounts of tungsten are used in lamp and radio-tube filaments, X-ray targets, and electrical contact points. Tungsten salts are used in the chemical, pigment, and tanning industries.

To conserve the supply of tungsten, molybdenum-tungsten high-speed steels (which contain 1 to 2 percent tungsten and 5 to 10 percent molybdenum) and sintered carbide materials (part of which are of the tungsten type) are being used successfully for many applications of tungsten high-speed steels; and molybdenum-manganese steel is being used for bullet cores.

WORLD PRODUCTION

Because of Government restrictions on the publication of statistics for many countries, few figures for 1940 and 1941 are available.

Argentina.—Argentina ranks second to Bolivia as a producer of tungsten in South America. All the tungsten produced is exported, and shipments abroad have increased phenomenally during the past decade. Exports in 1941 amounted to 1,897 short tons, of which 1,112 tons were shipped to the United States and 718 tons to Japan; 67 tons were destined to Germany in July, but the ship was intercepted by the British. Exports in 1940 were 1,585 short tons, of which 1,271 tons were shipped to the United States, 308 tons to Japan, and 6 tons to Sweden. Exports to Japan ceased after September 1941.

Bolivia.—Bolivia is the largest tungsten producer in South America. The first production recorded was in 1905, and the annual output through 1913 averaged less than 300 tons. During the World War of 1914–18, production averaged 2,471 metric tons (60 percent WO_3 basis) annually and attained a peak of 4,215 tons in 1917. From 1919 through 1934, annual production dropped to an average of about 500 tons, then increased progressively from 1,423 tons in 1935 to 4,353 tons in 1941. Of the total production in 1941, the Banco Minero de Bolivia (representative of the small miners) exported 1,625 tons, Cie. Aramayo de Mines en Bolivie 1,067 tons, International Mining Co. 760 tons, Bolivian Tin & Tungsten Mines 318 tons, and several small producers 583 tons.

Burma.—Burma ranks second to China as a producer of tungsten. Recent production figures are not available, but 9,025 metric tons (60 percent WO_3 basis) were produced in 1939 compared with 7,796 tons in 1938.

Canada.—Tungsten occurs in many parts of Canada in association with gold ores, and during 1941 shipments of tungsten ores were made to the Department of Mines for treatment. A small plant for the recovery of scheelite is being erected at the Hollinger mine at Timmins, Ontario.

China.—Production figures for China, principal producing country, are not available for 1941, but 9,474 short tons (60 percent WO_3 basis) were received in the United States.

World production of tungsten ores, 1937–41, by countries, in metric tons of concentrates containing 60 percent WO_3 [1]

[1] In addition to countries listed, tungsten ore is produced in Japan, U. S. S. R., and Western Australia, but data on production are not available.
[2] Data not available.
[3] Less than 1 ton.
[4] January to June, inclusive.

Chosen.—According to Emmons:[11]

To coordinate and develop the tungsten production of Chosen, arrangements have been announced to center the control of all the tungsten mines of the peninsula in three principal companies, the Japan Mining Co., Japan High Cycle Heavy Industry Co., and Kobayashi Mining Co. The consumption of all domestic tungsten will be limited to seven principal manufacturing concerns. The Kobayashi Mining Co. is reported to be exploiting several newly developed tungsten deposits and to be constructing an ore sorting mill at Yotoku in South Heian Province. A new tungsten deposit is also being developed by Kongo Special Mining Co. in the Diamond Mountains (Kongo San).

Peru.—The only tungsten deposits of proved economic importance in Peru are in the Provinces of Santiago de Chuco and Pallasca in the Departments of La Libertad and Ancash in the west-central part of Peru. These deposits became important during the 1914–18 war period, when a peak production of 532 metric tons of concentrates was attained in 1916. After hostilities ceased, the operators were unable to compete with other sources of supply, and production declined to low figures. The Peruvian deposits have again become increasingly active, and since 1937 production has advanced from 78 metric tons to 337 tons in 1941.

Spain.—Production of wolframite in Spain was 504 metric tons in 1941 compared with 299 tons in 1940. The greater part (426 tons) of the 1941 production came from the Province of Coruña, the remainder being divided between the Provinces of Badajoz and Salamanca. The wolframite boom led to much prospecting and surface mining of hitherto deserted mines in Badajoz Province, where output in December 1941 was five times that of the total for the other 11 months.

BAUXITE AND ALUMINUM

By Herbert A. Franke and M. E. Trought [1]

SUMMARY OUTLINE

SUMMARY

Production (618,134,000 pounds) and consumption (605,577,231 pounds) of primary aluminum in 1941 advanced 50 and 33 percent, respectively, over those in 1940. However, 1941 was only the beginning of a new era for aluminum as the Nation prepared for its greatest war, which could not be won unless vast quantities of the light, strong metal were available to build bombers, pursuit planes, and other implements of modern warfare. To meet this objective the War Production Board has recommended expansion of annual domestic aluminum capacity to approximately 2,100,000,000 pounds and the procurement of metal from Canada at a rate that would reach 450,000,000 pounds in 1943. In 1942 production and consumption of aluminum should substantially exceed 1,000,000,000 pounds; by 1943 production is expected to be about double that, and consumption should approach 2,500,000,000 pounds.

Highlights of the industry in 1941 included the following: Mandatory priorities were placed on aluminum in February; the secondary aluminum industry became completely disorganized early in the year following three successive price reductions on primary metal in 1940; as military requirements rose during the summer virtually all civilian uses for aluminum were stopped; and on October 1 the fourth price reduction within 19 months (by the Aluminum Co. of America) brought the price of primary aluminum from 17 cents to 15 cents a pound. In December the United States was at war with Japan, Germany, and Italy and thankful that the private aluminum expansion program and the first Government one were well on their way. The Aluminum Co. of America increased production capacity at all five of its aluminum reduction plants, notably at Vancouver, Wash.,

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

and the Reynolds Metals Co. became the second substantial domestic producer of aluminum. The Aluminum Co.'s expansion program was completed in March 1942, and in May 1942 three new Government-owned aluminum plants (under the first expansion program) had already started operations.

Recovery of secondary aluminum increased 33 percent in 1941. Imports and exports of crude and semicrude aluminum in 1941 declined 26 and 73 percent, respectively, compared with 1940.

Production (894,174 long tons) and consumption (1,721,475 long tons) of bauxite in 1941 increased 104 and 61 percent, respectively, compared with 1940. As with aluminum production, the large output of bauxite in 1941 will be dwarfed by that of 1942 and 1943. Original plans called for the domestic production of 1,899,000 tons (1,344,000 of low-silica and 555,000 of high-silica ore) and the importation of 1,386,000 tons of bauxite in 1942, and the production of 3,290,000 tons (1,600,000 of low-silica and 1,690,000 of high-silica ore) and the importation of 1,800,000 tons of bauxite in 1943. Enemy submarines began sinking South American bauxite cargoes destined to aluminum plants in the United States and Canada in the spring of 1942, which probably will necessitate an "all-out" domestic mining program and greatly increase the bauxite-production goals set above (possibly to 6,000,000 tons or more) for Arkansas and other Southern States. Owing to the shipping crisis, an allocation order was issued July 7, 1942, effective August 1, 1942, to conserve and direct the distribution of bauxite and alumina. It is estimated that domestic consumption of bauxite will reach about 2,600,000 tons in 1942 and 5,100,000 tons or more in 1943.

In 1941 imports of bauxite (1,116,546 long tons, 88 percent of which came from Surinam) exceeded those in 1940 by 77 percent. Exports (dried equivalent) rose 82 percent. Of the domestic and foreign bauxite consumed, the aluminum industry used 69 percent; chemical, 17 percent; abrasive, 12 percent; and other industries, 2 percent. Compared with 1940, the aluminum industry increased its consumption of bauxite approximately 82 percent, and the abrasive and chemical industries each used better than 60 percent more ore. Domestic output was equivalent to 36 percent and imports to 64 percent of the total ore consumed. Shipments from Arkansas mines comprised 91 percent of the total domestic production, and output in Georgia, Alabama, and Virginia rose substantially above that of 1940. Although the minimum quoted price for domestic bauxite advanced 17 percent, the average value actually received for all grades of ore shipped was only slightly above that for 1940.

World production of bauxite is believed to have increased 36 percent and of aluminum 40 percent in 1941. Axis and Allied production of aluminum was "neck and neck" in 1941, but in 1942 and 1943 United Nations output is expected to greatly exceed that of the Axis.

Salient statistics of the bauxite and aluminum industries in the United States, 1939–41

	1939	1940	1941
Bauxite:			
Production (mine shipments) [1] ....long tons..	375,307	438,913	894,174

BAUXITE

PRODUCTION

An all-time record was established in 1941, when production (mine shipments converted to dried basis) of bauxite in the United States increased 104 percent in quantity and 108 percent in value over that of 1940. Production rose 90 percent in Arkansas, 593 percent in Alabama, 653 percent in Georgia, and 739 percent in Virginia.

Mines in Saline and Pulaski Counties, Ark., produced 91 percent of the total domestic output in 1941. American Cyanamid & Chemical Corporation operated the Townsend, Cleveland, Ozark Nos. 24 and 28, Globe, Rauch, and Heckler properties. Large-scale stripping operations were conducted at the Townsend and Ozark No. 24 mines, chiefly during August 1941 when considerable ore was mined and stock-piled. Consolidated Chemical Industries, Inc., abandoned its Gates lease (Alexander No. 2 mine) during the summer and began to develop a new property in Pulaski County. American Cyanamid & Chemical Corporation later acquired the Gates lease. Crouch Mining Co., Inc. (owned by General Abrasives Co.), continued development work underground at its new Young mine in Saline County and completed installing a large, new, rotary calcining kiln in December 1941, which substantially increased its processing capacity. Dixie Bauxite Co., Inc., continued operations at its Dixie No. 2 mine and began underground mining on the Wright property, formerly worked by the Pulaski Bauxite Co. Dulin Bauxite Co., Inc., started to produce early in 1941 on the Reichardt lease several miles south of Little Rock and early in 1942 began to develop the Harley and Thorpe leases and to construct a processing plant at Sweet Home. Republic Mining & Manufacturing Co. (Aluminum Co. of America subsidiary), the principal domestic producer, extended its previous open-pit and underground mining operations and commenced or completed stripping overburden from bauxite on large areas in secs. 14 and 15, T. 2 S., R. 14 W. (including the Alexander Hill deposit). Reynolds Mining Corporation acquired bauxite-mining rights to several properties in Saline and Pulaski Counties and did extensive geological and other exploratory work thereon in 1941.

Bauxite shipped from mines in the United States, 1937-41, by States

[1] Includes small quantity of activated. [2] Includes Virginia. [3] Includes sintered.

Bauxite mining was active in Alabama during 1941. In the Barbour-Henry County area the Bauxite Co. of Alabama and the Barbour Bauxite Co. commenced new operations, and the Republic Co. and Floridin Co. also were active. J. C. Hebble started mining ore in a new field 3 miles south of Ashville in St. Clair County. In Sumter County, Ga., American Cyanamid & Chemical Corporation resumed activities by opening up the Thig Pen mine, and Benjamin Easterlin shipped a small quantity of ore from his property. Early in 1942 the General Ore Co., Inc., started operations near Silver Creek, Floyd County, Ga., and near Eufaula, Barbour County, Ala. In Virginia the Republic Co. shipped ore in 1941 from the Lightner and Allen mines, Augusta County.

Following a general canvass by the Bureau of Mines in March 1941 of current bauxite production, capacity, and proved reserves, the Bureau of Mines and the Geological Survey made a detailed preliminary survey of domestic bauxite resources. Results of this survey were published in November 1941.

Estimated bauxite reserves of the United States [1] in long tons and by grade,[2] and alumina content, in percent

State	Grade and alumina content, percent				
	A (55 plus)	B (50 to 55)	C (45 to 50)	D (30 to 45)	Total
Arkansas	9,090,000	8,443,000	7,803,000	1,918,000	27,254,000
Alabama	16,000	79,000	33,000	230,000	358,000
Georgia	237,000	311,000	481,000		1,029,000
Mississippi		23,000	100,000	200,000	323,000
Tennessee		36,000	22,000		58,000
Virginia		6,000			6,000
Total	9,343,000	8,898,000	8 439,000	2,348,000	29,028,000

[1] Thoenen, J. R., and Burchard, E. F., Bauxite Resources of the United States. Bureau of Mines Rept. of Investigations 3598, 1941, p. 39.
[2] Grades are as follows A = 55 plus percent Al_2O_3, minus 7 percent SiO_2, B = 50 to 55 percent Al_2O_3, 7 to 15 percent SiO_2; C = 45 to 50 percent Al_2O_3, 16 to 30 percent SiO_2, D = 30 to 45 percent Al_2O_3, high in silica and iron.

With the tremendous aluminum-production program planned, known domestic reserves of high-grade bauxite would be exhausted within a few years if dependence were placed solely thereon. In view of this critical situation Congress appropriated funds in the fall of 1941 for a more comprehensive investigation by the Bureau of Mines and Geological Survey of the occurrence, extent, and quality of domestic bauxite, alunite, and high-alumina clay deposits.

Because of the limited reserves of high-grade ore, large quantities of marginal or high-silica bauxite (B and C grades) must be mined in 1942 and 1943, chiefly in Arkansas, for the new Hurricane Creek and Baton Rouge alumina plants. Stripping the overburden with power shovels and Le Tourneau and Euclid wagons and other development work on the low-grade deposits were started in 1941 by the Republic Mining & Manufacturing Co., American Cyanamid & Chemical Corporation, and Reynolds Mining Corporation.

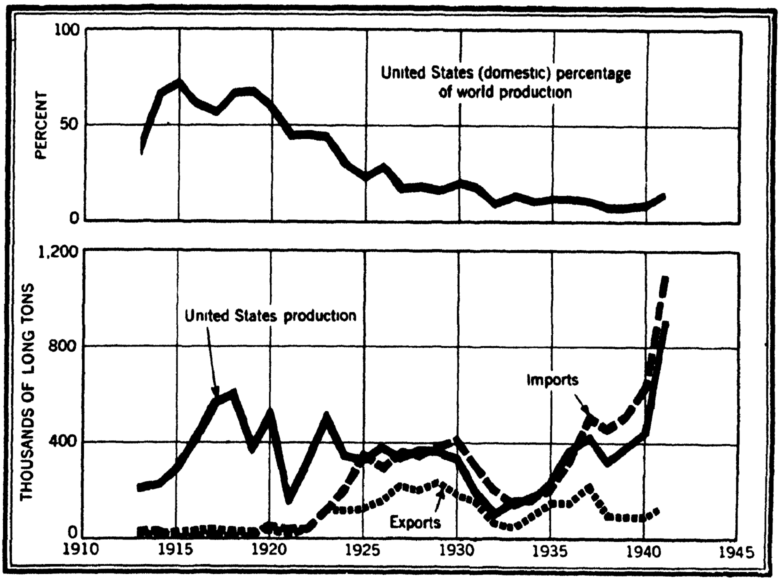

FIGURE 1.—Trends in production, imports, and exports of bauxite, 1913–41.

Stocks of bauxite on hand at mines and processing plants on December 31, 1941, totaled 157,600 long tons (dried-bauxite equivalent) compared with 168,600 tons on December 31, 1940. Stocks at consumers' plants increased from 221,900 tons at the beginning of the year to 541,600 tons at the end of the year.

CONSUMPTION

Actual domestic consumption of bauxite (as determined by special monthly consumer surveys conducted by the Bureau of Mines for Federal war agencies) totaled 1,721,475 tons (dried-bauxite equivalent) in 1941 and compares with an apparent consumption of 1,072,000 tons in 1940. Both quantities include exports to Canada, as virtually all bauxite shipped there during those years was to American-owned abrasive plants for the manufacture of crude abrasives reimported

into the United States for final manufacture and consumption. Consumption of the 1,721,475 tons was as follows: Aluminum industry, 1,190,710 tons; chemical, 295,348; abrasive (including refractories), 210,060; and cement, oil-refining, steel, and ferro-alloy industries, 25,357 tons. Consumption of bauxite "as shipped" totaled 1,642,458 tons and consisted of 1,478,509 tons of dried bauxite, 132,962 tons of calcined, and 30,987 tons of undried and activated ore. Of this bauxite, 64 percent was foreign and 36 percent domestic ore. The aluminum industry used 94 percent and the chemical industry 5 percent of the foreign ore. About 1 percent of the foreign bauxite was employed in abrasives, cements, and other uses.

Apparent domestic consumption, shown in the table below, is presented from two different points of view; and apparent consumption within the United States does not correspond with the data above, inasmuch as the calculations are based upon "shipments" to domestic plants and do not consider fluctuations in consumers' stocks.

Shipments, imports, exports, and apparent consumption of bauxite in the United States, 1937–41, in long tons

[Dried-bauxite equivalent]

Year	Domestic shipments from mines and processing plants to industry			Imports	Exports	Apparent consumption within United States	Apparent consumption, including shipments to Canada for processing [1]
	Arkansas	Alabama and Georgia [2]	Total				
1937	415,050	17,614	432,664	507,423	210,657	729,430	921,000
1938	275,078	17,253	292,331	455,693	90,341	657,683	732,000
1939	335,647	13,689	349,336	520,179	86,540	782,975	867,000
1940	437,595	[2] 11,603	449,198	629,552	120,055	958,695	1,072,000

Total quantity	383,529	432,664	267,479	292,331	312,036	349,336	391,480	449,198	874,761	937,616
Total value	$2,722,403		$1,823,307		$2,448,038		$3,075,317		$6,155,714	

[1] Includes crude, dried, and calcined, 1937–41; also activated, 1938–41, and sintered, 1939–41.
[2] Includes some ore shipped to the abrasive and chemical industries.
[3] Small quantity of bauxite shipped to makers of refractories probably included under "Abrasive."

The foregoing table shows only shipments to consuming industries of domestic bauxite and excludes foreign ore.

Aluminum.—Consumption of bauxite by the aluminum industry in 1941 increased approximately 82 percent over that in 1940 and comprised 69 percent of all the domestic and foreign ore used. The industry employed dried and undried ore from Arkansas, Alabama, Surinam, British Guiana, the Netherlands Indies, and Brazil. Estimated bauxite consumption in 1942 is expected to be at least 40 percent above that in 1941.

Abrasive and refractory.—Manufacturers of crude aluminous abrasive pigs in Canada and the United States received approximately 64 percent more domestic bauxite in 1941 than in 1940, being consigned 15 percent of all the domestic ore shipped. Except for a small quantity from British Guiana, all of the calcined and sintered ore employed came from Arkansas. The industry's 1942 ore requirements are expected to exceed those of 1941 by about 40 percent. The use of bauxite in refractories is combined with abrasives. In 1941 the consumption of special aluminous refractory products increased substantially in the steel, glass, ship, and other industries.

Chemical.—The chemical industry used 62 percent more bauxite in 1941 than in 1940 and 17 percent of all the domestic and foreign ore consumed. Shipments of domestic bauxite from mines and processing plants to the chemical industry increased 74 percent. Consumption by the industry totaled 295,348 long tons of bauxite, but this includes ore used to make some aluminum chemicals other than those shown in the table. Ore used to manufacture the salts and alumina shown in the table totaled only about 236,900 tons. In addition to bauxite, aluminum salts producers reported consuming 21,841 short tons of alumina (dry equivalent), 4,170 tons of aluminum, and a relatively small quantity of clay, alunite, beryl, and chromite residue. Manufacturers estimated that their 1942 bauxite consumption would exceed that of 1941 by almost 10 percent.

Production and shipments of aluminum salts increased 21 and 22 percent, respectively, in 1941; of alumina (for use other than in aluminum), 106 and 113 percent, respectively. Of this alumina, only 39 percent was consumed by the producers of aluminum salts; the remainder was used in the manufacture of abrasives, refractories, petroleum, spark plugs, glass, rubber, paints,[2] and various other products.

[1] 147 pounds.

In 1941 the General Chemical Co. started to produce aluminum sulfate in a new plant at Vancouver, Wash., and the Stauffer Chemical Co. built a new plant at Portland, Oreg.

Oil refining, cement, and other.—The use of thermally activated bauxite as an adsorbent and catalyst in the petroleum industry continued to expand in 1941 and is expected to enlarge substantially in 1942 as production of high-octane aviation gasoline increases and the manufacture of synthetic rubber commences. The manufacture of quick-setting, early-strength calcium aluminate cement and the fluxing of ferro-alloys also required more bauxite.

PRICES

In 1941 the average selling price, f. o. b. mines and processing plants, was $4.31 per long ton for crude (undried) bauxite, $5.63 for

crushed dried bauxite, $13.79 for calcined bauxite, and $41.09 for activated bauxite. The average value for all grades of domestic ores as shipped was $5.94 per ton ($5.93 in 1940). The Metals Reserve Co. plans to purchase marginal grades of bauxite in 1942 for the new Arkansas alumina plant on a sliding price scale, providing a bonus for ore high in alumina and a penalty for ore high in silica. Nominal quotations on domestic, chemical, crushed and dried bauxite rose from $6.00–$8.00 in 1940 to $7.00–$8.50 in 1941.

FOREIGN TRADE

Imports of bauxite in 1941 topped the peak set in 1940 by 77 percent, and exports (dry equivalent) advanced 82 percent. Of the imports, 982,515 tons came from Surinam, 84,683 from British Guiana, 36,082 from Netherlands Indies, and 13,266 from Brazil. By customs districts, importations were as follows: 680,827 tons to Mobile, 263,519 to New Orleans, 40,098 to Philadelphia, 10,446 to Massachusetts, 121,648 to Virginia, and 8 to New York. Of the 1941 exports, 119,261 tons were classified as bauxite and other aluminum ores, 15,462 tons as other bauxite concentrates, and 23 tons as alumina; all of these were consigned to Canada, except for less than 1 ton of alumina sent to Brazil.

Bauxite imported into and exported from the United States, 1937–41

Year	Imports for consumption [1] [2]		Exports (including bauxite concentrates) [3]		Year	Imports for consumption [1] [2]		Exports (including bauxite concentrates) [3]	
	Long tons	Value	Long tons	Value		Long tons	Value	Long tons	Value

[1] Also "alumina" as follows: 1937, 182 long tons valued at $16,461; 1938, 64 tons, $5,464; 1939, 1 ton, $432; 1940, 11 tons, $1,743; 1941, 60 tons, $5,544.
[2] Chiefly dried ore. As shipped.

ALUMINUM

PRODUCTION

Primary.—The production of 618,134,000 pounds of primary aluminum in 1941, 50 percent more than in 1940, initiated an aluminum-expansion program destined to reach an annual rate of approximately 2,100,000,000 pounds in 1943, a further advancement of 240 percent. By the end of 1941 the annual production rate totaled approximately 760,000,000 pounds, and in 1942 actual domestic output should total substantially more than 1,000,000,000 pounds. The five aluminum-reduction plants of the Aluminum Co. of America supplied the larger part of the 1941 output. The Reynolds Metals Co. became the first new company to produce primary metal when it began operations at Listerhill, Ala., in June 1941 and at Longview, Wash., in September 1941. Of the Aluminum Co. output, 35 percent was made at Alcoa, Tenn.; 24 percent at Massena, N. Y.; 22 percent at Vancouver, Wash.; 13 percent at Badin, N. C.; and 6 percent at

Niagara Falls, N. Y. Of the Reynolds production, Listerhill, Ala., accounted for 79 percent and Longview, Wash., for 21 percent. Value of the aluminum produced in 1941 averaged 16.24 cents a pound compared with 18.25 cents in 1940. Greater fabricating capacity paced the enlarged metal-producing program.

Although the Government made heavy financial commitments for the expansion of aluminum facilities, virtually all of the increased metal production and fabrication completed by the Aluminum Co. of America during 1941 resulted from expenditures of the company's own money (a $215,000,000 expansion program was begun in 1937). Funds for plants of the Reynolds Metals Co. were obtained from the Reconstruction Finance Corporation, which took the company's existent aluminum-fabricating facilities as security. On June 27, 1941, the Government announced that more aluminum would be needed to fulfill Army-Navy and Lend-Lease requirements, and late in the summer of 1941 it began to let contracts for the construction and operation of its own aluminum plants through the Defense Plant Corporation.[3]

The first Government expansion program (of June 27, 1941) for 303,000 short tons of aluminum was followed by a second expansion program (announced February 26, 1942) providing for an additional 320,000 tons of metal. The Aluminum Co. of America was the first company to enter into a contract with the Defense Plant Corporation (August 19, 1941) for the construction and operation of a 200,000-ton (annual) alumina plant (later extended to 500,000 tons and recently expanded again to 650,000 tons) at Hurricane Creek, near Bauxite, Ark., utilizing low-grade bauxite and of three reduction plants to produce a total of 160,000 tons of aluminum. The Aluminum Co. also agreed to build additional plants to be operated by others. The contract provides that the company design and construct the plants at cost but without fee or profit and that it operate them under a 5-year lease and pay the corporation 85 percent of the net profits from operation. Either party can extend its own capacity; the lease can be canceled; and an adjustment in price of the metal will be made if unreasonable profits are attained. In concluding negotiations the Aluminum Co. of America agreed to reduce the price on ingot aluminum after September 30, 1941, from 17 cents to 15 cents a pound.

The Office of Production Management originally recommended that the remainder of the aluminum-producing capacity under the first expansion be divided among four other companies—Reynolds Metals Co., Olin Corporation, Bohn Aluminum & Brass Co., and Union Carbide & Carbon Co. This program did not materialize exactly as planned, and only the first two of these firms decided to enter into the production of primary aluminum. Reynolds finally decided to add only 27,000 tons of capacity to its Listerhill works, and Olin was allocated 15,000 tons, which later was increased to 20,000 tons. Olin's subsidiary, Kalunite, Inc., was authorized to build a 10,000-ton alumina plant based upon alunite, which later was extended to 30,000-ton capacity. The Aluminum Co. was allocated the production capacity that remained on the first expansion program, which when revised to conform to the company's standard design brought its share of this program to 256,000 tons.

---

[3] Franke, Herbert A., The Aluminum Situation: Min. and Met., vol. 22, No. 419, November 1941, pp. 528-532.

As the War Production Board (which superseded the Office of Production Management January 24, 1942) realized that the vast increase in the Nation's aluminum facilities would still not be enough to assure essential materials for the greatly increased aircraft, munition, and other vital war programs, plans were announced for a second expansion in aluminum facilities. This provided for three new reduction plants and extensions to three others, and for another alumina plant. All of this capacity was turned over to the Aluminum Co. for construction and operation. The table shows the existent and projected alumina and aluminum program (as of August 1, 1942), which, when completed, will give the Government ownership of 51 percent of the alumina and 57 percent of the aluminum capacity of the country.

Projected annual alumina- and aluminum-producing capacity of the United States in 1943, in thousands of short tons

[1] First expansion program.
[2] Second expansion program.
[3] Government-financed.

Under its own privately financed program the Aluminum Co. of America started or completed during 1941 and the early part of 1942 expansion of aluminum reduction facilities at Alcoa, Tenn., Badin, N. C., and Vancouver, Wash.; another addition to its alumina plant at Mobile, Ala.; more capacity to produce castings (13,800 tons more a year), forgings (19,200 tons), extrusions (3,000 tons), tubing (18,000 tons), and rivets (1,000 tons); a large, new, strong-alloy sheet mill of 180,000 short tons capacity a year at Alcoa, Tenn.; a second blooming and rod mill at Massena, N. Y., to supply 120,000 tons a year of forging stock and rod, bar, and wire; the stripping of large bodies of bauxite ore at Bauxite, Ark.; two rotary bauxite-drying kilns and mining equipment at Bauxite, Ark.; bauxite drying and mining capacity at Moengo Hill and Paranam, Surinam; acquisition of eighty 70-ton covered hopper railroad cars on a 5-year lease and ten new ore-carrying vessels;

and construction of a dam and power house of 27,000 Kv.-a. at Glenville, N. C., and of a hydroelectric project of 54,000 Kv.-a. at Nantahala, N. C. In August 1941 the company voluntarily turned over to the Tennessee Valley Authority for coordinated operation or integration its five hydroelectric developments on the Little Tennessee River and also transferred to it the great Fontana dam site, where the Government is now constructing a 225,000-kilowatt hydroelectric plant. In February 1942 cabling machinery at Massena, N. Y., made idle by the diversion of aluminum to more essential war purposes, was sold to the Anaconda Wire & Cable Co.

Under the aluminum expansion programs initiated by the Government, the Aluminum Co. of America undertook to design, construct, and operate all the new capacity proposed under the first- and second-expansion programs (or for 1,150,000 tons of alumina and 576,000 tons of aluminum) except for 30,000 tons of alumina and 47,000 tons of aluminum allocated to Kalunite, Inc., Olin Corporation, and Reynolds Metals Co. In addition to alumina- and aluminum-producing plants, the expansion programs provide for more fabricating, carbon electrode, synthetic cryolite, aluminum fluoride, power, and other capacity. The power program includes construction of a new steam-electric generating plant with 80,000-kilowatt output and a gas-engine-powered D. C. generating plant of 81,000-kilowatt installed capacity at Jones Mills, Ark. Extension of fabricating capacity involves the production of more forgings, rivets, extrusions, wire, rod, bar, tubing, and sheet (including high-strength alloy sheet). Outstanding among the fabricating projects are two Government-financed aluminum sheet mills—at Chicago, Ill. (of 120,000-ton annual capacity), designed and constructed by the Aluminum Co., and at Spokane, Wash. (of 120,000-ton capacity), designed and constructed by the United Engineering & Foundry Co. (except for ingot casting and furnaces, which will be designed and installed by the Aluminum Co.).

A strike of Congress of Industrial Organizations workers at the Edgewater (N. J.) rolling mill of the Aluminum Co. lasted from March 12 to March 24, 1941. On April 26, 1941, the company made a general wage (and salary) increase to all its employees which amounted to 10 cents an hour when added to that of October 1, 1939. In June 1941 the aluminum and aircraft programs again were threatened with strikes. Congress of Industrial Organizations workers walked out at the Cleveland plant of the Aluminum Co. (and the Detroit plants of the Bohn Aluminum & Brass Co.) demanding further wage increases. The Cleveland strike ended after 2 days and resulted in a 1-cent-an-hour wage increase. After 10 days the Detroit strikers returned to work and submitted their wage demands to further negotiations before the National Defense Mediation Board. In July 1941 the Congress of Industrial Organizations demanded that an 18-cent-an-hour sectional wage differential between workers in northern and southern aluminum plants be eliminated. After other negotiations failed and a strike threatened, the case was certified to the National Defense Mediation Board on August 16, 1941. On February 12, 1942, the National War Labor Board ordered gradual elimination of the wage differential between the Aluminum Co.'s northern and southern plants, which was accepted by the company

"under protest." The Board also ruled that a premium should be paid for night work.

In October 1941 Federal Judge Francis G. Caffey handed down a decision on the monopoly charges filed against the Aluminum Co. of America by the Antitrust Division of the Department of Justice on April 23, 1937. The decision favored the company and cleared it of the charges of monopoly, conspiracy, and other violations of the Sherman Act. Monopolization charges covered bauxite, water power, alumina, virgin aluminum pig and ingot, castings, cooking utensils, pistons, extrusions and structural shapes, foil, miscellaneous fabricated articles, sheets, and cables. The judge reserved jurisdiction for the court on the matter of selling sheet and cable below cost to restrain competition or to compete with copper. He ruled that there was no conspiracy between the Aluminum Co. and Aluminium, Ltd., or any foreign producer and that the charges of misconduct were not pertinent to the Sherman Act. On December 17, 1941, Judge Caffey denied Assistant Attorney General Thurman Arnold's motion to have the court's oral decision on the case designated as the court's findings of fact and conclusions of law for the purpose of speeding appeals before the United States Supreme Court because he held that the charges of price fixing, monopoly, and restraint of trade alleged by the Government had not been sustained.

During 1941 the Reynolds Metals Co., Federal Reserve Bank Building, Richmond, Va., completed an aluminum plant (95,000 tons annual capacity) and aluminum reduction plants at Listerhill, Ala. (18,000 tons), and Longview, Wash. (27,000 tons). Reynolds aluminum-fabricating facilities were greatly increased in capacity by one sheet-rolling mill and one rod and shape mill at Listerhill, and one sheet-rolling mill, one rod mill, and one extrusion plant at Louisville, Ky. The company expansion program provides for enlargement of the reduction plant at Listerhill and increasing its ingot capacity to 45,000 tons, which is scheduled to be brought into operation during the summer of 1942. The company further mortgaged its plants to secure Reconstruction Finance Corporation loans for expansion of its aluminum program. Arrangements with the Defense Plant Corporation provided for the 24,000-ton aluminum-alloy extrusion plant at Lousiville, Ky., and for the 39,000-ton aluminum-alloy sheet and blooming mill at Listerhill, Ala. The fabricating facilities at Listerhill are operated under the name of the Reynolds Alloys Co.

Reynolds is reported to have prospected, drilled, and proved reserves of over 3,000,000 tons of domestic bauxite. In May 1941 Reynolds signed a 12-year contract with the N. V. Billiton Maatschappij for 6,000,000 tons of Surinam bauxite in addition to the earlier provision for bauxite made with the same company for shipments from Bintan, Netherlands Indies, and one made with the Companhia Geral de Minas of Brazil. The first ore shipments from Surinam are expected to arrive in the summer of 1942. The company is opening an underground mine in Arkansas which will commence producing bauxite for the Government alumina plant there late in the fall of 1942.

The Olin Corporation, East Alton, Ill., owner of the Western Cartridge Co., began construction of a 20,000-ton aluminum reduction plant at Tacoma, Wash., which is scheduled to begin production

early in the fall of 1942. Its subsidiary (Kalunite, Inc.) began work on an alumina plant of 30,000 tons capacity at Salt Lake City, Utah, to use alunite from Marysvale, Utah. The Bureau of Mines made a survey [4] which indicated domestic reserves of alunite totaling 9,400,000 short tons, contained in 21,900,000 tons of rock averaging a minimum of 30 percent alunite. Reserves of high-grade material, containing 50 percent minimum alunite content, were estimated at only 2,400,000 tons, contained in 3,350,000 tons of rock.

Other companies which expanded or were enlarging facilities in connection with the aluminum program (chiefly through the Defense Plant Corporation) were: Extruded Metals Defense Corporation—a 21,000-ton (annual) aluminum-alloy extrusion plant at Grand Rapids, Mich.; Bohn Aluminum & Brass Corporation—a 22,000-ton aluminum-alloy extrusion plant at Adrian, Mich., and another of 7,800-ton capacity at Los Angeles, Calif.; Willys Overland Motors, Inc.—a 1,800-ton aluminum-alloy forging plant at Toledo, Ohio; Chrysler Corporation and Ford Motor Co.—aluminum-alloy forging facilities at Detroit and Dearborn, Mich., respectively; General Motors Corporation—forging plants at Saginaw, Mich., and Muncie, Ind.; Naval Aircraft Factory and the Weatherhead Co.—forging plants at Philadelphia, Pa., and Cleveland, Ohio, respectively; National Bronze & Aluminum Foundry Co. and Packard Motor Car Co.—aluminum-alloy casting facilities at Cleveland, Ohio, and Detroit, Mich., respectively; Pennsylvania Salt Mfg. Co.—a 10,000-ton synthetic cryolite and 3,000-ton aluminum fluoride plant at Cornwells Heights, Pa.; General Chemical Co.—an aluminum fluoride plant at Marcus Hook, Pa.; and Revere Copper & Brass, Inc.—a 27,000-ton aluminum-alloy forging plant at Rome, N. Y.

Secondary.—Recovery of secondary aluminum in 1941 totaled 106,857 short tons compared with 80,362 tons in 1940 and 53,947 tons in 1939. The 106,857 tons recovered from secondary sources included 8,308 tons of pure metal (98.5+ percent), 97,614 tons of aluminum alloys, and 935 tons of aluminum in chemical products (784 in aluminum chloride and 151 in aluminum sulfate). Production in the form of secondary aluminum ingot totaled 83,933 tons (68,489 in 1940). The secondary aluminum recovered in 1941 required the consumption of 126,447 tons of aluminum scrap, 45,329 tons or 36 percent of which was old scrap (53,265 tons or 57 percent in 1940), and 81,118 tons or 64 percent new scrap (39,587 or 43 percent in 1940). Remelters, smelters, and refineries used 79 percent of this scrap; aluminum rolling mills, 13 percent; and foundries and other manufacturers, 8 percent.

CONSUMPTION

Apparent domestic consumption of primary aluminum in 1941 advanced 33 percent over that in 1940. Consumption of secondary aluminum increased at approximately the same rate.

1941	618,134,000	100,395,000	26,715,155	14,808,924	605,577,231	213,714,000	34,707,153

[1] Data not available on fluctuations in consumers' stocks. Withdrawals from producers' stocks totaled 3,483,000 pounds in 1937, 62,886,000 in 1939, and 60,375,000 in 1940; additions to producers' stocks totaled 112,959,000 pounds in 1938 and 24,463,000 in 1941

[2] Based upon average price of primary aluminum as reported to Bureau of Mines.

[3] Crude and semicrude, some of which may be secondary aluminum.

Of the primary metal consumed in 1941, the transportation industry used 63 percent compared with 40 percent in 1940 and only 29 percent from 1933 to 1938. The aviation industry employed the greater part of that used in the transportation field plus a considerable portion of the 19 percent allocated to the foundry and metal-working business. Production of military and commercial aircraft in the United States in the first month of each year had increased from 157 in 1939 to 279 in 1940 and 1,107 in 1941. In September 1941 production totaled 1,942 planes and on June 26, 1942, the President announced that the output for May 1942 reached nearly 4,000 planes. The President's airplane-production program announced January 6, 1942, calls for 60,000 planes in 1942 and 125,000 in 1943—45,000 and 100,000, respectively, of the heavier combat type. Aluminum is said to constitute 54 to 80 percent of the weight of an airplane (including the motor). The percentage break-down of primary aluminum used by industry in 1941 was approximately as follows: Transportation (air, water, and land), 63 percent; foundry and metal working, 19 percent; machinery and electrical appliances, 6 percent; chemical, 5 percent; building construction, 3 percent; ferrous and nonferrous metallurgy, 2 percent; and cooking utensils, 1 percent. No new metal was used for the manufacture of electrical conductors and food and beverage products. According to the American Iron and Steel Institute, the steel industry consumed 3,957,359 pounds of aluminum in October 1941 (averaging 0.562 pound per ton of steel), and it will need about 60,000,000 pounds of aluminum annually, chiefly to deoxidize and purify molten steel. Remelted aluminum scrap satisfies the major part of these requirements.

PRICES

Despite the great demand for aluminum, on October 1, 1941, the Aluminum Co. of America reduced the base price of primary aluminum 2 cents, bringing down the open-market quotation in New York for

lots of 10,000 pounds or more, 99-percent plus pure ingot aluminum, delivered, to 15 cents a pound. The new price included the extension of additional transportation allowances on shipments of ingot and

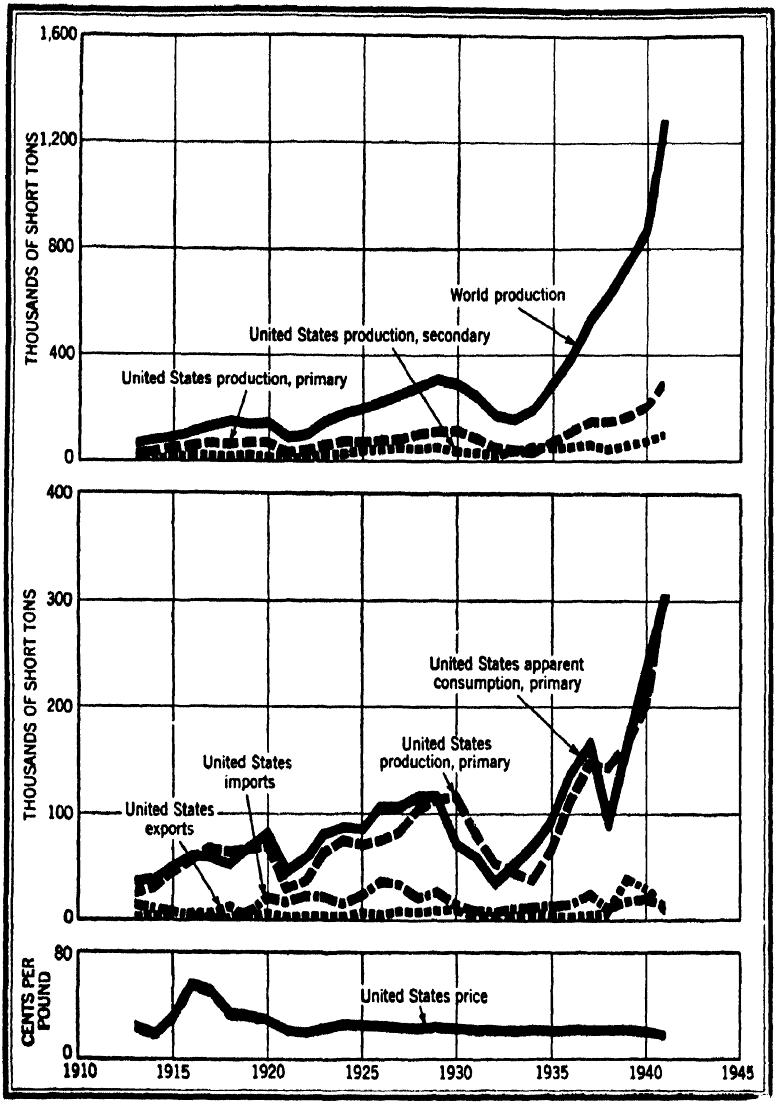

FIGURE 2.—Trends in production, imports and exports, apparent consumption, and average quoted prices of aluminum, 1913–41. Price is for No. 1 virgin 98–99 percent at New York through 1929, thereafter for 99-percent-plus virgin ingot, as reported by American Metal Market.

certain basic fabricated products to destinations west of the Mississippi River. Deductions allowed for transportation charges on orders of 500 pounds or more of one product cannot exceed the lowest carload rate of rail freight.

Within less than 2 years the price of aluminum has dropped 5 cents—from 20 cents a pound to 19 cents on March 25, 1940; from 19 cents to 18 on August 1, 1940; from 18 cents to 17 on November 18, 1940, and from 17 cents to 15 on October 1, 1941. Corresponding reductions in fabricated products also were made, and in May 1942 the Office of Price Administration announced that in August 1942 the Aluminum Co. would make further substantial reductions in its prices of fabricated products, particularly sheet, castings, and forgings. The price reductions on aluminum are attributed to massproduction, manufacturing improvements, and lower operating costs arising from research.

Chaotic conditions prevailed in the secondary or scrap-aluminum industry early in 1941 owing to the 1940 price reductions on primary aluminum and the maximum price schedules set by the Office of Price Administration and Civilian Supply. The Government set a maximum price of 11 cents on cast and forged scrap when sold by makers, 12 cents when sold by dealers, and 13 and 14½ cents, respectively, on pure clippings and cable, f. o. b. point of shipment. Prices of 17 cents and 16 cents, respectively, were established on secondary aluminum ingot 98 percent pure and on No. 12 alloy. According to Metal Statistics, 1942, dealers' buying prices per pound in New York for the principal grades of domestic aluminum scrap in 1941 averaged 10.76 cents for cast aluminum (8.95 cents in 1940) and 13.00 cents for new aluminum clippings (14.47 cents in 1940). The average selling price of remelted metal, 98½ to 99 percent grade, was 17.36 cents (18.74 cents in 1940), and of No. 12 alloy, No. 2 grade, 16.37 cents (14.66 cents in 1940).

FOREIGN TRADE

Imports and exports of crude and semicrude aluminum in 1941 were 26 and 73 percent less, respectively, than in 1940. The value of imports and exports of manufactured aluminum products decreased 51 and 54 percent, respectively. Imports (exclusive of scrap) constituted only 4 percent of the apparent consumption of primary aluminum in 1941. Of the imports of crude (12,830 short tons), 12,802 tons came from Canada and 28 from Chile; of semicrude (528 tons), all came from Canada; and of scrap (55 tons), 20 tons came from Cuba, 11 from Mexico, 6 from the United Kingdom, 5 from Jamaica, and 1 from Canada.

Of the crude aluminum exported in 1941 (750 short tons), 331 tons went to Brazil, 178 to Argentina, 45 to the United Kingdom, 83 to Canada, 28 to the Netherlands Indies, 26 to the Union of South Africa, 19 to China, 17 to Hong Kong, and 16 to Uruguay; of semicrude (6,655 tons), 2,903 tons went to the United Kingdom, 1,779 to U. S. S. R., 1,261 to Australia, and 201 to Canada; and of scrap (57 tons), 34 tons went to Canada and 21 to Brazil.

Aluminum imported for consumption in the United States, 1939–41, by classes

Class	1939		1940		1941	
	Pounds	Value	Pounds	Value	Pounds	Value

TECHNOLOGIC DEVELOPMENTS

Outstanding developments in technology in 1941 centered about the mass production of aluminum—the greatly increased recovery of ingots; the fabrication, upon a volume basis, of aluminum-alloy sheet, forgings, castings, rods, bars, and rivets; and the advancements in using low-grade bauxite, alunite, and clay.

One of the most important advancements in technology in the aluminum industry probably is under way at the Government's new

Hurricane Creek alumina plant near Bauxite, Ark. A combination Bayer and lime-soda-sinter process has been developed that is expected to yield a much higher percentage recovery of the alumina contained in bauxite.[5] Low-grade Arkansas bauxite will be used, which probably will average 13 to 14 percent silica compared with currently used high-grade Arkansas and South American bauxite averaging only about 5 percent silica. In the process developed by the Aluminum Co. in its East St. Louis pilot plant, high-silica bauxite (actually bauxite and clay) will be treated directly by the Bayer process (without prior washing) and the tailings or red mud subjected to a lime-soda sintering operation requiring the addition of lime and some soda ash. The sintered product will be leached and its liquors added to the Bayer process liquors. The Bayer process also has been improved by adding starch to the caustic soda solution to assist settling (U. S. Patent 2,280,998).

At Salt Lake City, Utah, a plant is under construction that will use the Kalunite process to extract alumina from alunite[6] or aluminum-bearing clays. By this process, crushed alunite rock (containing at least 20 percent alumina) first is roasted to drive off combined water, and the soluble residue is dissolved in a mixture of sulfuric acid and return liquor. Potassium alum is crystallized from the solution and decomposed in an autoclave to form basic alum and dilute sulfuric acid. The basic alum then is decomposed by heating to 1,000° C. Potassium sulfate is leached from this sintered residue, leaving the insoluble finished alumina. Potash and sulfur dioxide are obtained as byproducts.

Further developments in progress on the recovery of alumina from domestic raw materials include work by the Phelps Dodge Corporation on the fines from Morenci copper-ore mill tailings (potash-alum process); the Monolith Portland Cement Co. on clay (a lime-soda sinter process producing alumina and cement); the Tennessee Valley Authority on clay (a sulfuric acid process); Kalunite, Inc., on clay and alunite (sulfuric acid process); the War Metallurgy Committee of the National Academy of Sciences and the Bureau of Mines on clay and alunite (modified Pedersen process); the Aluminum Co. of America on clay and Bayer-process red mud (lime-soda treatment); and the Bureau of Mines on lime-soda sintering of high-silica bauxite and clay as well as on beneficiation of bauxite and alunite. To date, the Bureau's work on the beneficiation of submarginal bauxite shows that for some ores careful grinding and desliming suffices, other ores require gravity concentration to remove iron and titanium minerals, and still other bauxites require flotation or flotation and gravity concentration. Oleic acid and paper-mill fatty acid (tallol) proved the best reagents to collect the gibbsite, the principal extractable alumina mineral in bauxite.[7] Tests of the Seailles alumina process for the treatment of high-silica bauxite indicated that it was impracticable and uneconomic. By means of flotation, alunite was readily separated from quartz, the principal impurity.[8] The Bureau worked out

the details of a lime-soda-sinter process and assembled it in the form of a flow sheet, and construction of a pilot plant based upon it was begun. Work to date indicates that a lime-soda-sinter or a lime-sinter-soda-extract process may prove most practicable for the recovery of alumina from clay. A method developed by Arthur Hixson of Columbia University for the extraction of alumina from clay (U. S. Patent 2,249,761) involves roasting and subsequent treatment with hydrochloric acid and isopropyl ether, and one by Alfred R. Globus specifies the treatment of clay with sulfuric acid and then with excess sodium hydroxide.

Despite some advantages claimed for the Soderberg electrode,[9] it has been found more expedient in the expansion program to use chiefly the old-style pots and prebaked carbon block electrodes. Remelters increased the recovery of aluminum from scrap in 1941 by briquetting before melting and by using fluxes.[10] Additional research is recommended on prevention of the explosibility of aluminum powder and other metal dusts.[11] Improvements in methods of converting power from alternating to direct current by means of the mercury rectifier have greatly facilitated the rapid growth of the aluminum and other electrochemical industries.[12] The use of bauxite as a catalyst and catalyst carrier and of anhydrous aluminum chloride[13] in the production of high-octane aviation gasoline increased in importance.

Representative of the trend in fabrication is the new, mile-long, semicontinuous hot-strip mill (North mill) of the Aluminum Co. of America at Alcoa, Tenn., which simulates hot-strip steel roll-mill practices. Strong aluminum-alloy sheet 48 to 120 inches wide can be rolled for the aircraft industry at the North mill at the rate of 180,000 tons annually by means of a two-high, reversible, hot-roll mill followed by a single-stand and a four-stand tandem mill. The strong-alloy sheet mill of the Reynolds Metals Co. at Listerhill, Ala., also depicts a more modern trend in aluminum fabrication. This plant includes a single-stand hot reversible mill, a single-stand cold, and a four-stand cold mill. A new technique is the mass production of compound curved surfaces in sheet, as for large airframe skin panels, in which forming takes place by controlled drawing actions applied to a moving sheet while it travels at selected speeds.[14] There was a trend in favor of forgings in place of sand castings in 1941, and the use of press rather than hammer forgings increased for small articles. More hot-pressed or kneaded forging stock went into the manufacture of crankcases and other aircraft products. Development of forged or pressed aircraft cylinder heads by the Wright Aeronautical Corporation showed great promise. The firm uses hydraulic mechanical presses and upsetters instead of drop hammers on aluminum-alloy cast ingot or extruded bar stock.[15] To take care of the great demands for forging stock and rods, bars, and wire, the

Aluminum Co. started construction of a second, and plans for a third, blooming mill. Although production of extrusions increased, the advance probably was not as great as that in Europe, where extruded products are widely used as forging stock. During 1941 sand casting foundries were more highly mechanized, and there was a trend toward the mass and straight-line production of only one product, such as cylinder heads, in a single plant (as by Buick, Ford, and Aluminum Co.). The Antioch plaster-mold process for the production of highly stressed aluminum castings to unusually close tolerances was further improved.[16] The manufacture of permanent mold [17] and die castings increased substantially, largely because of the aircraft program. Many zinc die-casting machines were converted to produce aluminum-alloy castings. The production of rivets greatly increased, and new blind or pull-through and explosive rivets [18] were introduced for airplane work in places that are not readily accessible. Mass fabrication led to better understanding of the aluminum alloys, of which 24S (both bare and Alclad) was the most widely used. Alloys 2S, 3S, and 52S, available in controlled tempers, were produced by cold-work from hot-mill slab, while alloys 17S and 24S were heat-treated and aged at room temperatures and alloys 53S, and 61S were heat-treated and artificially aged at moderately elevated temperatures to develop maximum strength. Tests showed that aluminum-base alloys containing varying amounts of magnesium usually exhibit marked resistance to the action of alkaline corrosion.[19] Spot welding of aluminum alloys was applied more to stressed members of airframes.[20]

NATIONAL DEFENSE AND WAR MEASURES

When it became obvious that aluminum requirements for military purposes had been underestimated, the Office of Production Management placed the metal under mandatory priorities—on February 24, 1941.[21] This order, No. M-1, effective March 22, 1941, was superseded by No. M-1-f, on February 14, 1942, which further restricted the delivery, processing, use, and inventories of aluminum. Ceiling prices were set on scrap and secondary ingot during March 1941 by the Price Stabilization Division of the Office of Production Management in order to maintain price stability and prevent excessive and speculative price increases. This price order was amended in May, June, August, October, and November 1941. Regulations governing the disposition and use of aluminum scrap were promulgated April 11, 1941, in Order M-1-b, which was amended June 10, 1941 (Order M-1-c) and January 7, 1942 (Order M-1-d). A survey by the Bureau of Mines in April 1941 showed that domestic bauxite production could be increased from limited reserves in an emergency.

The National Academy of Sciences began an investigation of possible substitutes for aluminum early in 1941, and in May 1941 it was

announced that civilian and nonessential uses for the metal would be seriously curtailed as the armed forces would absorb virtually the entire metal output. As a result of the President's new heavy-bomber program, aluminum began to present a more serious problem. Apparently military needs had not been fully appreciated. Underestimation of requirements and the shortage were laid in part to failure to provide adequate working inventories for processing of the metal, to foresee the extent of indirect military needs, to obtain aluminum scrap from secondary markets, and to make allowance for the reduction in imports from Canada.

In June 1941 the Office of Production Management directed the Office of Civilian Defense to conduct a Nation-wide collection of old and unwanted aluminum. The campaign, however, was disappointing, as an anticipated collection of 20,000,000 pounds of aluminum actually yielded only 11,173,979 pounds of scrap, which contained but 6,398,051 pounds of recoverable aluminum. The poor yield was attributed to inadequate preparation by the Office of Civilian Defense and to the fact that cooperation from scrap dealers was not requested.

On June 27, 1941, the Office of Production Management made recommendations for the first aluminum-expansion program—to increase domestic aluminum productive capacity to 1,400,000,000 pounds and to procure an additional 200,000,000 pounds of metal from Canada. The alumina capacity provided for in this program was subsequently increased from 400,000,000 pounds to 1,300,000,000. Contracts and commitments for the construction of these new plants began to be let in August 1941 by the Defense Plant Corporation. The first contract was made with the Aluminum Co. of America.

In the fall of 1941 punitive action was taken against violators of aluminum priorities—companies that had diverted much-needed aluminum from vital defense or war production to nonessential uses. The aluminum program was threatened several times by strikes as well as by the shortage of boats for bringing bauxite from South America. High priority ratings for necessary materials were granted by the Division of Priorities for the construction of new aluminum plants.

On January 23, 1942, Conservation Order M-1-e became effective, prohibiting the use of aluminum except in the manufacture of specific items. Rearrangement of maximum prices for aluminum "plant" scrap were made by the Office of Price Administration on January 13, 1942, to facilitate operation of the segregation order (M-1-d), issued January 7, 1942. On March 10, 1942, allocations were placed on aluminum paint and pigments (Order M-1-g). In February 1942 the Director of Industry Operations of the War Production Board (formerly Office of Production Management) ordered all idle aluminum inventories in the hands of fabricators sold to the Government. On February 16, 1942, the United States Department of the Interior proposed a vast expansion program for mineral and power developments in the West, which included the aluminum industry.

On February 26, 1942, the Aluminum and Magnesium Branch, Division of Materials, War Production Board, announced a second aluminum expansion program to assure the Nation a supply of metal ample to produce the airplanes requested by the President. This program provided for an increase in annual domestic aluminum production capacity to 2,100,000,000 pounds, which (with Canadian

imports) should make available a supply of over 2,500,000,000 pounds of primary metal a year. The contracts made May 2 and July 15, 1941, by the Metals Reserve Co. with the Aluminum Co. of Canada, Ltd., call for the total delivery of 340,000 metric tons of aluminum before the end of 1944. The new expansion program also involves the annual remelting and reworking of about 400,000,000 pounds of recovered scrap and a very considerable increase in fabricating facilities.

In May 1942 the three reduction plants provided by the first Government expansion program began operations. The Metals Reserve Co. started purchasing high-silica Arkansas bauxite in the spring of 1942 to supply the Government's new Hurricane Creek alumina plant, scheduled to start operations in July 1942. Enemy submarine torpedoing of boats carrying bauxite from South America to the United States and Canada resulted in the issuance of Order M-1-h on July 7, 1942, which allocates for any use all bauxite, both domestic and foreign, containing less than 15 percent silica and all alumina, effective August 1, 1942.

Power for the original, first, and second aluminum expansion programs and for other industries presented the Government with a serious problem, and during the first part of 1941 the Office of Production Management set up a special branch to study power requirements. Total power generated in 1941 for public and industrial use is said to have totaled approximately 212,000,000,000 kw.-hr. To supply expanding war industries in 1943, total requirements have been placed as high as 300,000,000,000 kw.-hr. During 1941 many power projects were completed or extended, and construction of new hydroelectric and steam plants was begun. Outstanding projects included those by the United States Department of the Interior agencies in the West (Bonneville, Grand Coulee, and Boulder Dams)[22] and the Tennessee Valley Authority in the South.[23] Other power expedients were adopted, such as connecting transmission lines or grid systems, power poolings, curtailment of nonessential uses, and the operation of reserve generating capacity in industrial and big city areas. An unprecedented drought in the South during 1941 brought out a call for voluntary reduction in the consumption of power during the summer and early fall. The Federal Power Commission directed immediate construction of connecting power links. Heavy rains late in the fall of 1941, however, relieved the power situation in the South.

WORLD BAUXITE AND ALUMINUM INDUSTRIES

Aluminum is expected to play a leading role in winning the present world conflict. By the end of 1943 production and consumption of both aluminum and magnesium will reach a rate undreamed of before the war. After peace is restored it is expected that a substantial part of the vast productive capacity for these two light metals will be utilized at the expense of other metals because of their greater relative

abundance in the earth's crust, their utility and diversified usage, and a more advantageous price position (already competitively stronger upon a volume basis).[24]

World production of bauxite is estimated to have reached approximately 6,396,900 metric tons in 1941, 36 percent more than that in 1940 and 66 percent more than that in the pre-war year 1938.

Armstrong & Co., George S., An Engineering Interpretation of the Economic and Financial Aspects of American Industry: Vol. 3, The Light Metal Industries—Aluminum, Magnesium, New York, 1942, [illegible] pp.

The aluminum made in 1941 is believed to have totaled about 1,150,600 metric tons, 40 percent more than in 1940 and 99 percent more than in 1938. Of the world output in 1941, it is thought that production under the control or domination of Germany in Europe was about 485,200 tons; under total Axis control, 575,200 tons (or 50 percent); and under total Allied control, 575,400 tons (or 50 percent). The annual rate of production in 1943–44 may be about as follows: German European control, 721,000 tons; total Axis control, 921,000 tons (36 percent); and total Allied control,1,620, 000 tons (64 percent).

REVIEW BY COUNTRIES

Australia.—Extensive geological surveys conducted by the Department of Mines reveal the occurrence of substantial reserves of low-grade bauxite and alunite in Australia. New South Wales ore analyzed ranges from 25 to 68 percent Al_2O_3, 2 to 39 percent Fe_2O_3, and up to 20 percent SiO_2. Sulphates Pty., Ltd., now mining bauxite at Boolarra, Victoria, and the White Metals (Australia) Pty., Ltd., are interested in developing various other ore deposits, including those at Ouse, Tasmania (reserves reported at 2,000,000 tons with 48 percent Al_2O_3); Mount Tambourine, Queensland; and Wingello, New South Wales. The Australian Aluminium Co. Pty., Ltd., began to operate its aluminum strip and sheet rolling mill at Granville, New South Wales, on May 1, 1941, and the construction of another fabricating mill in Australia is under consideration. The use of aluminum for other than authorized purposes was prohibited by the Minister of Munitions on December 17, 1941, The National Aluminium Mining & Smelting Co. proposes to produce 5,000 tons of alumina annually at Port Kembla, using bauxite from Wingello, New South Wales, and to locate a reduction plant at Sydney.

Brazil.—Companhia Electro-Chimica Brasileira plans to construct a 10,000-ton alumina and a 2,000-ton reduction plant at Saramenha, a short distance from Ouro Preto, Minas Gerais. A priority rating for equipment has been granted the company in the United States. Bauxite will be obtained from nearby ore deposits, and power will be secured from two hydroelectric plants on the Rio Maynart, one of which is in operation and the other under construction. Companhia Brasileiro de Aluminio, S. A., plans to develop the Poços de Caldas bauxite deposits and to produce aluminum at plants to be built near São Paulo, but it now appears likely that the shortage of critical materials in the United States will hinder early completion of this project. The Bank of Brazil, with Government authorization, granted the company a loan repayable within 12 years. The fabrication of aluminum (chiefly cooking utensils) in São Paulo was paralyzed in the summer of 1941 as importation of the metal from the United States virtually ceased. Exports of bauxite from Brazil in 1941 (chiefly to the United States) totaled 14,365 metric tons compared with only 82 tons in 1940.

British Guiana.—Exports of bauxite by the Demerara Bauxite Co., Ltd., during 1941 totaled 1,072,617 long tons, of which 908,125 tons went to Canada, 112,815 to the United States, and 51,677 to the United Kingdom. The company had five rotary drying kilns in operation at MacKenzie during the summer of 1941 producing 4,800 tons of dried ore daily. The Berbice Co., Ltd., plans to start shipping

bauxite in the summer of 1942 from its property about 130 miles up the Berbice River. Dried ore is to be barged down to Everton, whence it will be loaded into ocean-going vessels. Establishment of an alumina and aluminum plant in British Guiana has been proposed by American interests.

Canada.—Compared with 1941, Canadian aluminum production is expected to increase about 60 percent in 1942 and more than double in 1943. A 5-day strike at the Arvida reduction plant of the Aluminum Co. of Canada, Ltd., in July was a serious set-back to output in 1941, as the molten metal in the pots solidified when the power was shut off and caused a production delay of several weeks. Aluminum-fabricating facilities also have been greatly expanded in Canada, principally at Kingston, Ontario, where strong-alloy sheet, extrusions, tubing, and forgings are made, partly for United States consumption. Rolled screw machine and rivet stock is produced at Shawinigan Falls, Quebec, and sheet and castings at Toronto, Ontario.

In 1943 one-sixth of all the electric power of the Dominion will be used to produce aluminum. The Aluminum Co. of Canada, Ltd., is further developing the hydroelectric power resources of the Lake St. John-Chicoutimi district and also is investigating available power resources in Manitoba with a view to constructing a new plant in that Province. In the Lake St. John-Chicoutimi district the company will spend $30,000,000 building a channel from its dam at Chute-á-Caron to the mouth of the Shipshaw River, where a hydroelectric plant is to be constructed capable of generating 820,000 hp. (compared with 265,000 hp. now produced at Chute-á-Caron). The proposed facilities could ultimately be extended to 1,000,000 hp. The American Nepheline Corporation (subsidiary of Ventures, Ltd.) is experimenting on the extraction of alumina, potash, and soda ash by a lime-sinter process from nepheline syenite derived from the Bancroft, Haliburton, and Lakefield areas of Ontario. To reduce the sailing time of ocean-going vessels, late in the summer of 1941 South American bauxite began to be discharged at Portland, Maine, for movement by rail to Arvida. Early in 1942 sinkings by enemy submarines began seriously to affect these bauxite cargoes, and bauxite and alumina were imported from the United States.

France.—French aluminum production is believed to have failed in reaching its objective of 70,000 tons in 1941 because of the lack of railroad transportation, lack of skilled labor, inadequate coal supply, and hydroelectric power and labor troubles. Early in 1942 production was reduced two-thirds owing to power difficulties; these, however, were soon overcome, and production returned to normal in April. Within the next 2 or 3 years the large Genissiat Dam on the Rhône River is expected to be completed, and it will be able to supply an enormous quantity of hydroelectric power. Most of the aluminum is now shipped to Germany or used in France to produce war equipment for Germany. The Groupement de Repartition de la Bauxite was recently founded in France by Pechiney, Ugine, Union des Bauxites, Bauxites de France, Bauxites du Midi, Ciments de Lafarge et du Teil, and Aluminium du Sud-Ouest to undertake the distribution and control the utilization of all bauxite. Axis European production of aluminum depends partly on France, not only for metal but for bauxite and alumina, which are shipped to Germany, Switzerland, Italy, Norway, and other countries for processing. Southern France is reported to be shipping bauxite to Italy at the rate of 250 truckloads daily.

Germany.—German and Austrian aluminum production in 1941 has been estimated at 300,000 to 350,000 tons. Greater production is believed to have been retarded by Germany's lack of hydroelectric power, the heavy demand by other industries for steam power, the lack of miners to extract more coal, bombings by the British Royal Air Force, and inadequate transportation facilities. Although most of the aluminum output is derived from bauxite mined in Hungary, France, and the Balkan countries, two German plants (Lautawerk and Lippe or Lünen) are reported jointly producing 50,000 tons of alumina annually from clay, and two other plants (Lautawerk and Horrem near Cologne, owned by Lurgie Thermie G. m. b. H. of Metallgesellschaft A. G.) are making virtually all of the aluminum-silicon or Silumin alloy (12 percent silicon) needed by direct thermal reduction of clay with carbon.[45] Germany greatly increased its supply of aluminum in its conquest of other European countries, particularly in the acquisition of France and Norway. Three new aluminum plants with a total capacity of 50,000 tons are reported under construction in Austria—two on the Inn River below the Innwerke plant and the third on the Enns River. It is reported unofficially that Germany obtained 38,000 tons of bauxite and 10,000 tons of aluminum from Unoccupied France between January 15 and March 1, 1941. On June 1, 1941, the price of aluminum was reduced from 133 reichsmarks to 127 per 100 kilograms. The import duty on alumina (4 reichsmarks per 100 kilograms) for aluminum production was removed March 1, 1942.

Gold Coast.—A bauxite mine was opened in the Colony about 50 miles northwest of Dunkwa, whence the ore is hauled by truck to Dunkwa and by rail to Takoradi.

Honduras.—Unconfirmed reports mention the occurrence of bauxite in southern Honduras.

Hungary.—The production capacity of aluminum plants owned by Manfried Weiss and the Kohlenbergbau, A. G., was expanded substantially in 1941. The Ungarische Bauxitgruben, A. G., increased its production of bauxite about 50 percent in 1941 over that of 1940 (647,000 tons) and plans to build an alumina (20,000 tons) and aluminum reduction (10,000 tons) works at Ajka, near Veszprem, as well as an aluminum-fabricating plant at Stuhlweissenberg. During the latter part of 1941 the Hungarian Price Commissariat ordered an increase in taxes on 99.3- to 99.5-percent aluminum and on semifinished materials from Pengos 27 to Pengos 49 per 10 pounds. The maximum selling price for raw aluminum, including taxes, was increased from Pengos 280–297 to Pengos 302–310 per 10 pounds.

India, British.—The new 20,000-ton alumina and 3,000-ton reduction plant of the Aluminium Corporation of India, Ltd., at Asansol, Bengal, started operations early in 1941. Indian bauxite is used in the alumina plant, and Söderberg electrodes are employed in the reduction works. The Aluminium Production Co. of India, Ltd., still plans to construct aluminum-producing facilities at Alwaye, North Travancore. The Development Department of the Government of Madras reveals that many million tons of workable bauxite of various grades occur in the Shevaroy Hills about 207 miles southwest of Madras.

[45] Haenni, P. M., Light Alloys in Modern Warfare: Canadian Metals and Met. Ind., vol. 5, No. 2, February 1942, pp. 36–42.

Italy.—According to Giornale d'Italia, the Italian production of aluminum would reach 50,000 metric tons in 1941, 60,000 in 1942, and 100,000 by 1943 and 1944. Production in 1941, by plants, is estimated as follows: Porto Marghera (Venice), 20,000 tons; Bolzano, 15,000 tons; Mori, 10,000 tons; and Borgofranco, 5,000 tons. In May 1941 Trafilerie e Punterie di Cogoleto was authorized to enlarge its Cogoleto fabricating plant. Società Edison (Milan), a power company, received permission to build a reduction plant with an annual capacity of 10,000 tons. Although the aluminum industry is still expanding, the shortage of electric power has caused great difficulties, and Italy exports some of its alumina to Germany in payment for necessary machinery.

Japan.—Few official data on the Japanese aluminum industry have been available since 1937. The conquest of Malaya and the fall of Singapore made available to Japan large reserves of high-grade bauxite on Bintan Island and in Johore, and Japanese industrial concerns are reported to have started immediate development of the deposits. The Aluminium Co. of the South Seas is reported working bauxite deposits on Palao Island, where reserves are reputed to total 10,000,000 tons. Early in 1941 the Japanese Ministry of Industry placed Yen 30,000,000 at the disposal of the aluminum industry for developing bauxite deposits in Northern China and Indochina and on Panope Island. Expansion of the Japanese aluminum industry was urged by the Government in 1937, and by the end of 1941 Japan is believed to have had aluminum-producing facilities totaling about 140,000 to 150,000 metric tons. Aluminum production in 1941 is estimated at 90,000 tons, but some observers place output as high as 150,000 tons. In 1941 the aluminum industry was consolidated further by the Government. The Toyo Aluminium Co., belonging to the Mitsui group, was amalgamated with the Sei-Sen Chemical Co., a subsidiary of the Japan Soda Co.

Following is a list of the principal Japanese aluminum companies, with some of their plant locations and annual capacities (in metric tons):

Company:	*Alumina*	*Aluminum*
Japan Light Metals Co.	Shimizu, Shizuoka Pref. (120,000).	Kambara, Shizuoka Pref (27,000 to 36,000). Niigata, Niigata Pref. (18,000 to 27,000).
Japan Electrochemical Industry Co.	Koyasu, Nagano Pref.	Omachi, Nagano Pref. (20,000).
Japan Aluminium Co.	Takao, Taiwan (20,000).	Takao, Taiwan (10,000). Karenko, Taiwan (2,000 to 6,000).
Manchuria Light Metals Mfg. Co.	Fushun, Manchuria (25,000 to 45,000).	Fushun, Manchuria (12,000). Antung, Manchuria (9,000).
Sumitomo Aluminium Reduction Co.	Niihama, Shikoku Island, Ehime Pref. (18,000).	Kaneko-Mura, Niigun, Shikoku Island; Ehime Pref. (9,000).
Japan Soda Co.	Takaoka, Toyama Pref.	Takaoka, Toyama Pref. (16,000 to 20,000).
Korea Nitrogen Fertilizer Co.	Konan, Chosen	Konan, Chosen (6,000).
Japan-Manchuria Co.	Iwase, Toyama Pref.	Koriyama, Fukushima Pref. (5,000).
Toyo (Oriental) Aluminium Co.	Omuto, Kyushu Island, Fukuoka Pref.	Takaoka, Toyama Pref. (6,000).

Another alumina plant is said to be located at Kurosaki, Kyushu Island.

Netherlands Indies.—The N. V. Billiton Maatschappij produced 171,821 metric tons of bauxite on the Island of Bintan in 1941. Of the 165,571 tons shipped, 130,871 tons went to Japan, 25,000 to Australia, and 9,700 to the United States. Plans for the erection of hydroelectric, alumina, and aluminum plants in Sumatra were delayed in 1941 and later were upset by Japanese occupation of the Indies.

Norway.—A/S Nordag, registered on June 26, 1941, owned by Hansa Leichtmetall A. G., Berlin, and directed by Field Marshal Hermann Goering, has largely completed plans and has started preliminary work on aluminum plants and power stations at Sunndalsoyra, Ose, Tyin, Tyssedal, Sauda, Glomfjord, Eitreheim, and Lassedal. Before the Germans entered the Norwegian aluminum industry the reduction plants had about the following rated capacities: Tyssedal (Hardangerfjord), 6,000 tons; Haugvik (Glomfjord), 8,000; Hoyanger, 9,000; Eydehavn, 10,000; Vigeland, 4,000; and Stangfjord, 1,000. Apparently plans have been made to extend capacity at Glomfjord to 23,000 tons, commencing March 1, 1942; at Eitreheim to 8,000 tons, beginning May 1, 1942; and at Tyin to 22,000 tons, starting September 1, 1942. Alumina amounting to 60,000 tons annually is to be produced at Sauda (Rogalan), and amounting to 50,000 tons at Ordalstangen, Tyin. Work at Ordalstangen is scheduled to start July 1, 1942. Plans for the other sites are not completed. Another company involved in the expansion of Norwegian aluminum production to 130,000 tons annually is Nordisk Lettmetal A/S, controlled by I. G. Farbenindustrie. One of its reduction works will be at Skienfjord, in the neighborhood of the Norsk Hydro power installation at Heroya. This plant, however, will be supplied with power from a new hydroelectric plant to be built at Rjukan. The Norwegian Nitrogen Co. is said to be working in conjunction with the German concerns. Apparently the alumina is to be derived from bauxite obtained by rail and boat from Unoccupied France, Hungary, Yugoslavia, and Greece and from domestic labradorite.

Southern Rhodesia.—The manufacture of aluminum sulfate in South Africa by African Explosives & Industries, Ltd., was made possible by the discovery of a high-grade deposit of bauxite near Penhalonga, Southern Rhodesia.[26] The deposit is operated by the Wankie Colliery Co., Ltd., which experimented with the ore but found it unsuitable for the manufacture of refractory brick. A 5-year contract was then signed for supplying the Umbogintuini and Modderfontein chemical plants of African Explosives & Industries, Ltd. The ore in most places is overlain by not more than 20 feet of overburden and is worked by open-cut methods. From the drying plant the ore is bagged and shipped to Umtali whence it must be transported by truck, oxen, and wagon. The ore averages about 62 percent Al_2O_3, 6 percent SiO_2, 1 percent Fe_2O_3, 8 percent insolubles, and 1 percent moisture.

Spain.—Owing to the shortage of copper in Spain, aluminum production is to be increased and domestic bauxite deposits will be exploited. Mining has been carried on at intervals at Gijon, Asturias, and in the southwestern part of Barcelona, but the ore has heretofore been considered too low in grade and unsuitable for metallurgical

[26] South African Mining and Engineering Journal, The Penhalonga Bauxite Deposit: Vol. 52, No. 25 August 16, 1941, pp. 739–742.

purposes. A second aluminum reduction plant, of 8,000 tons annual capacity, is being built and eventually will operate on domestic raw material. The old reduction works at Sabinanigo is producing at a rate of 700 to 1,200 tons of aluminum annually.

Surinam.—Virtually all of the 1,180,000 long tons of bauxite exported from Surinam (Netherlands Guiana) in 1941 by the Surinaamsche Bauxite Maatschappij (subsidiary of Aluminum Co. of America) went to the United States. American troops occupied Surinam in November 1941, partly to protect the valuable bauxite deposits developed in the Moengo and Para Creek districts. N. V. Billiton Maatschappij has completed most of its mining installations and plans to ship bauxite from its deposits in the Para Creek district (near Paranam) to the Reynolds Metals Co. in the summer of 1942. The bauxite reserves of Surinam are reported adequate to last many years, and visible ore reserves of the Moengo Hill and Rorak regions alone have been estimated at 10,000,000 tons and 8,000,000 tons, respectively (ranging from 54 to 64 percent in Al_2O_3 content).

Sweden.—During the first half of 1941, Sweden was able to maintain an almost constant stock of aluminum, but in the latter half supplies were cut drastically. As a result, Svenska Aloxidverken A. B., a subsidiary of A. B. Svenska Aluminium Kompaniet, was formed to manage two projected new plants. Construction of a plant at Kubikenborg, near Sundsvall, northern Sweden, capable of producing 6,000 tons of alumina annually from Boliden andalusite, has been started and will be completed in the spring of 1942. A reduction plant is to be built at the same place with an annual capacity of 1,100 tons of metal. This plant will require about 2,000 tons of the locally produced alumina, and the remaining 4,000 tons will be shipped to the Månsbo reduction plant. Restrictions were placed on the use of aluminum in April 1941.

U. S. S. R.—Two of the three Soviet aluminum reduction plants (Dnepr with 35,000 tons capacity and Volkhov with 15,000 tons capacity) probably were destroyed before Germany invaded or attacked these two areas. Equipment from the Dnepr plant is believed to have been moved to the Kamensk or to another plant site in the Urals. The previously announced annual capacity of the Kamensk works was 50,000 tons.

United Kingdom.—Although small additional aluminum-producing facilities have been completed, the United Kingdom depends largely on Canada for its metal requirements.

Yugoslavia.—Output of bauxite in Croatia totaled 211,000 metric tons in 1941 compared with 271,000 tons in 1940. Croatia now possesses most of the Dalmatian-Hercegovinian mines, but the alumina and aluminum works at Lozovac are in Italian hands. Italy concluded an agreement with Croatia whereby the aluminum works at Lozovac will deliver a large part of its metal output to Croatia in return for bauxite. Construction of a 30,000-ton aluminum plant in Croatia is under consideration. A new bauxite deposit has been discovered near Brijeg in Slovakia.

MERCURY

By H. M. Meyer and A. W. Mitchell [1]

SUMMARY OUTLINE

SUMMARY

The Axis Powers were favored with supplies of mercury at the outset of the present World War, because Italy and Spain, the principal world sources, were closely associated with them. The development of alternate sources of supply to cover their requirements, therefore, was a problem their opponents had to solve. Since the war began, however, production in Western Hemisphere countries has increased until, for a time at least, the United Nations are relatively self-sufficient in this commodity for all essential purposes. There can be little question that the record-breaking high prices for mercury played their part in this outstanding achievement.

In 1939 the United States produced 18,633 flasks, Mexico 7,376 flasks, and Canada 6 flasks. By 1941 the production in the United States had reached 44,921 flasks and in Mexico 23,137 flasks. Data for Canada cannot be published, but it is well-known that a noteworthy contributor to world supplies has been developed and is producing large quantities.

Consumption in the United States during 1941 was 67 percent above that in 1940 and indicated that a new high record rate was established. The sharp upward trend in domestic production during 1940 continued in 1941 with diminished vigor; supplies from United States mines just sufficed to satisfy increased domestic needs but allowed no surplus for exportation. Export restrictions imposed in 1940 were effective in preventing needed metal from leaving the country, and an agreement reached in July 1941 assured retention of Mexican production in the Western Hemisphere. At the end of the year, supplies and requirements appeared to balance, with some metal available for stock-piling. Nevertheless, the probability of increased demands for war purposes led the Office of Production Management to consider means of reducing consumption of mercury in uses designated as nonessential.

[1] Monthly data on production, consumption, and stocks compiled by D. A. Wyatt.

These considerations eventuated in Conservation Order M-78, issued in January 1942 and discussed in more detail later in this report.

Domestic production of mercury amounted to 44,921 flasks in 1941 and was 19 percent above the total for 1940, which itself was more than double the rate that had obtained for a number of years immediately preceding. The 1940 and 1941 totals represent successive peaks in the annual production recorded since 1883.

General imports of mercury totaled 7,478 flasks in 1941 compared with 1,861 flasks in 1940; of the 1941 total, none was entered in the first 7 months, 750 flasks in August, 735 in September, none in October, 1,725 in November, and 4,268 in December. Immediately after the agreement with Mexico in July 1941, exports and production figures for that country dropped sharply. By the end of 1941, however, imports into the United States were exceeding the monthly rate of production in Mexico, indicating that any accumulated stocks in that country may have been in process of dissolution.

Exports dropped from 9,617 flasks in 1940 to 2,590 flasks in 1941, under the restrictions placed thereon in July 1940. The United Kingdom was the principal destination of mercury exported from the United States in both 1940 and 1941 but in 1941 took only a small fraction of the total taken in 1940– 598 flasks compared with 5,178 flasks. Japan received no mercury from the United States in 1941 compared with 1,598 flasks in 1940. It is significant that late in 1941 the United States received 210 flasks of mercury from Canada, now the only source of consequence in the British Empire, but shipped reduced quantities to the United Kingdom. This condition lends weight to the suggestion that the British need mercury products more seriously than they do the metal itself.

Despite the sharp upturn in domestic mercury consumption, the average quoted price in 1941 advanced somewhat less than 5 percent over that in 1940. The 1940 average had been the highest on record, but a new record was established in 1941. Further price gains in 1941 were discouraged by warnings issued twice during the year by the Office of Price Administration. Although the first warning was in March 1941, action with regard to the establishment of a price ceiling was delayed until February 1942. When action was taken, ample supplies for all foreseeable war needs were believed by the price agency to have been provided for and not to have been endangered by the price move

Salient statistics of the mercury industry in the United States, 1937–41

[Flasks of 76 pounds]

	1937	1938	1939	1940	1941
Production ... flasks	16,508	17,991	18,633	37,777	44,921
Number of producing mines	101	91	107	159	197
Average price per flask:					
New York	$90.18	$75.47	$103.91	$176.87	$185.02
London	$69.65	$66.92	$88.26	$201.10	$194.20
Imports for consumption:					
Pounds	1,437,712	179,522	265,944	12,971	588,228
Equivalent flasks	18,917	2,362	3,499	171	7,740
Exports:					
Pounds	34,485	54,161	91,780	730,877	196,837
Equivalent flasks	451	713	1,208	9,617	2,590
Apparent new supply ... flasks	35,000	19,600	20,900	[1] [2] 26,800	[1] 44,800

[1] Actual consumption as reported by consumers. [2] Revised figures.

Agreement with Mexican Government.—During July 1941 an agreement was reached with the Mexican Government whereby the United States was to obtain surplus production of certain materials, including mercury, for 18 months. Under the terms of the agreement, the United States was obliged to acquire all metal not sold through ordinary commercial channels in countries in the Western Hemisphere that had export restrictions similar to those that had recently been put into effect in Mexico; the obligation applied to quantities up to 125 percent of total exports of mercury from Mexico during the 18 months ended July 1, 1941. Purchases are being made for the United States by the Metals Reserve Co. The agreement provides for changing prices based upon quotations in the United States regarded by the United States Government as technically authoritative.

This agreement not only guaranteed the United States large additional supplies of strategic commodities but denied these commodities to an enemy country. Japan received 93 percent of all the mercury shipped from Mexico in the first 7 months of 1941, before the agreement was signed, but received none officially after August.

Import restrictions.—General Import Order M-63, which went into effect at 12:01 a. m., December 28, 1941, provides that unless otherwise authorized by the Office of Production Management (now War Production Board) all future contracts for imports of 13 strategic materials, including mercury, will be handled by the Metals Reserve Co. An amendment issued in 1942 added mercury-bearing ores and concentrates to the commodities covered by the order.

Conservation in use.—The need to provide enough mercury for all possible war uses led the Office of Production Management to study the problem of reducing or discontinuing consumption of mercury in uses considered nonessential. Its study resulted in Conservation Order M-78, issued January 23, 1942. This order restricted the use of mercury for carroting hat fur, for marine antifouling paint, thermometers (except industrial and scientific), treatment of green lumber (except Sitka spruce), turf fungicides, vermilion, wall switches for nonindustrial use, and wood preservatives from January 15 to March 31 to 50 percent of such use in a selected base period, described later. Beginning April 1, 1942, all use for the purposes mentioned was to be discontinued, unless otherwise specifically authorized by the Director of Priorities. Consumers of mercury for the following purposes were ordered to restrict their use to the percentages given, as follows: Fluorescent lamps, 100 percent; health supplies, 100; mercuric fulminate for commercial blasting caps, 125; mercuric fulminate for ammunition, 100; and thermometers (industrial and scientific), 100 percent. Other consumers were restricted to 80 percent. "Base period" meant, at the option of the manufacturer, either (1) the corresponding quarterly period in 1940 or (2) the first calendar quarter of 1941, provided that the same option should be used throughout the calendar year. Exceptions from the order primarily covered materials for delivery under war and Lend-Lease contracts.

Price control.—The price for mercury was subjected to ceiling limitations in February 1942, following a prolonged study during which there was official warning more than once that the price was too high. Price Schedule 93 of the Office of Price Administration provided that the maximum base price for California, Oregon, Washington, Idaho, Utah, Nevada, or Arizona was \$191 per 76-pound flask, f. o. b. point

of shipment; for Texas and Arkansas it was $193, f. o. b. point of shipment; for mercury produced outside the continental United States and Mexico and entering the United States through Pacific coast ports of entry, it was $191, and for Mexico it was $193, f. o. b. freight station in the United States at or nearest the point on the boundary at which the shipment enters the United States (duty, if any, included).

Other sections of the order placed limitations on the dealers', brokers', and agents' charges.

Stock-pile purchases.—Mercury produced in the United States was added to the stock pile of the Procurement Division of the Treasury Department in 1941. In the latter part of the year, metal from Mexico began to accumulate for the credit of the Metals Reserve Co. Stock-pile gains in 1942 will comprise metal obtained from other Western Hemisphere sources, as well as from domestic mines and Mexico.

Bureau of Mines and Geological Survey activities.—The Bureau of Mines explored mercury deposits in six scattered districts in Oregon that revealed about 150,000 tons of low-grade ore averaging 1.6 pounds of mercury per ton. In addition, 200,000 tons of possible ore of similar grade may be expected upon the basis of reasonable geological deductions. Low-grade deposits in California were explored by test pitting and rotary bucket, which outlined over 100,000 tons of ore averaging 1.6 pounds per ton. In Valley County, Idaho, diamond drilling has indicated over 400,000 tons averaging 2.7 pounds of mercury per ton, and very recently one diamond-drill hole penetrated 34 feet (24 feet, true thickness) averaging over 11 pounds of mercury per ton. The importance of the higher-grade strike cannot be gaged until surrounding holes have been drilled. Exploration has been started on the old mine at Black Butte, Oreg., in the hope that the virtually depleted reserves there might be augmented. Drilling along the New Idria fault was begun late in 1941. This drilling is in the nature of wildcatting upon the basis of geological evidence.

The Bureau's engineers investigated seven additional mercury deposits in Nevada, California, Idaho, and Oregon, which (it has been estimated) might contain 850,000 tons of ore averaging 2.3 pounds of mercury per ton. This estimate, of course, is speculative and will have to be verified by further exploration.

During 1941 the Geological Survey issued reports on the mercury deposits of San Luis Obispo County and southwestern Monterey County, Calif.;[2] Steens and Pueblo Mountains, southern Oregon;[3] and adjacent parts of Nevada, California, and Oregon.[4] Field work was completed and reports were in preparation on the Pike County (Ark.) district; the Opalite district, Malheur County, Oreg., and Humboldt County, Nev.; the Weiser district, southwestern Idaho; and the Morton district, Lewis County, Wash. In Nevada, field work also was completed in the Wildhorse district, Lander County, and the Antelope Springs district, Pershing County; and work was in progress in the Ivanhoe and Mount Tobin districts in Elko and Pershing Counties, respectively. In addition, several smaller districts and scattered prospects in Nevada were examined and mapped

[4] Ross, C. P., Some Quicksilver Prospects in Adjacent Parts of Nevada, California, and Oregon: Geol. Survey Bull. 931-B, 1941, pp. 23-37.

in cooperation with the Bureau of Mines in a comprehensive sampling project, which was continued into 1942. In California, field work was completed in eight separate areas: The Coso district, Inyo County; New Idria district, San Benito County; Stayton district, San Benito and Merced Counties; Parkfield district, Monterey County; Knoxville district, Napa, Yolo, and Lake Counties; southeastern Mayacmas district, Napa and Lake Counties; Panoche district, San Benito County; and Canon del Puerto (Phoenix) district, Stanislaus County. Some preliminary work was done in the New Almaden district, Santa Clara County, and many small deposits and prospects throughout the State were visited in a search for promising areas in which to do additional work as well as to bring earlier information up to date. At the end of the year, field work was in progress in California in the northwestern part of the Mayacmas district, Lake and Colusa Counties, and in the Patricks Creek district, Del Norte County. In the New Idria district, an exploratory drilling program was begun by the Bureau of Mines, with geologic guidance by the Geological Survey.

In southwestern Alaska, field work was completed on the mercury deposits of Sleitmut in the Georgetown district.

In Mexico, work was in progress on cinnabar-bearing placers near Guadalcazar in San Luis Potosi, and early in 1942 a detailed study was begun in the new mercury area near Fresnillo, Zacatecas.

The Bureau of Mines recently issued two publications [5] that discuss hazards in mercury mining.

PRICES

Quoted prices for mercury trended upward throughout 1941 and twice during the year were the target of warnings issued by the Office of Price Administration. The average monthly price in New York was $165.85 a flask in January 1941 and $199.65 in December. Only in 2 previous months—January and February 1916—had monthly average prices been higher than in December 1941; and the annual average of $185.02 for 1941 had never been exceeded. Despite the fact that prices had advanced from $84.41 in August 1939—the month before declaration of war in Europe—and the threats mentioned above, price-ceiling action was withheld until February 1942. Probably the delay was due to the hesitancy of the price agency to take any action that might seriously disturb the maintenance of a favorable balance between supplies and requirements for this metal. By the time action was taken, substantial quantities of new supplies were arriving from Mexico, and steps to conserve the use of mercury had been taken by the Office of Production Management.

Early in 1940 the cartel price for Italian and Spanish mercury was $200 a flask, f. o. b. ports of origin; it advanced to $250 a flask in December, where it remained throughout 1941.

The price for mercury in London was £48 a bottle (flask) in January 1941. In May a new control order was issued which called for maximum prices of £48 15s. a bottle for quantities of over 1 and less than 11 bottles and of £48 for larger quantities, ex-sellers' premises in both cases. Smaller lots and redistilled grades were entitled to higher prices. The Ministry of Supply also announced that it was

[1] Engineering and Mining Journal, New York

[2] Mining Journal (London) prices in terms of pounds sterling converted to American money by using average rates of exchange recorded by the Federal Reserve Board, through August 1939 and from April 1940 to the end of that year, during the intervening period prices were quoted in American money. Official prices, established early in May 1941, were £47 15s to £48 15s. per flask beyond the end of the year.

[3] London excess.

CONSUMPTION

The Bureau of Mines began to compile monthly data on consumption of mercury at the outset of the present World War—September 1939. Before that time, supplies of metal available for use were calculated by the conventional method of merely adding production to imports and deducting exports, if no stock figures were available. Figures for 5 years are shown in the following table, in which apparent new supply figures are given for 1937 to 1939 and consumption data for 1940 and 1941.

There seems little reason to question the indication that in 1941 mercury was consumed at a new high-record level. During the period of highest domestic production, 1877 and the years immediately preceding and succeeding, metal also was exported at a very high rate. Export figures before 1880, however, are not entirely satisfactory, and precise comparisons are impossible.

Supply of mercury in the United States, 1937–41, in flasks of 76 pounds

Year	Production	Imports for consumption	Exports	Apparent total new supply
1937	16,508	18,917	454	35,000
1938	17,991	2,362	713	19,600
1939	18,633	3,499	1,208	20,900
1940	37,777	171	9,617	[1, 2] 26,800
1941	44,921	7,740	2,590	[1] 44,800

[1] Actual consumption as reported by consumers. [2] Revised figures.

Requests for consumption data were revised in the middle of 1941 in order to obtain more detailed figures. Statistics for the first and second halves of the year, as reported to the Bureau of Mines, follow.

Mercury consumed in the United States in 1941, in flasks of 76 pounds

JANUARY TO JUNE

Use	Flasks	Use	Flasks
Drugs and chemicals	13,558	Felt manufacture	683
Fulminate	939	Other	1,131
Electrical apparatus	2,317		
Industrial and control instruments	1,456	Total	[1] 21,600
Vermilion	712		

JULY TO DECEMBER

Use	Flasks	Use	Flasks
Pharmaceuticals	2,679	As a catalyst or in electrolytic preparation of—	
Dental preparations	609		
Chemical preparations [2]	4,059	Chlorine and caustic soda	155
Agriculture	1,968	Acetic acid	825
Fulminate	1,601	Other	1,202
Electrical apparatus	2,379	Amalgamation	225
Industrial and control instruments	2,175	General laboratory use	175
Vermilion	510	Redistilled [3]	2,163
Antifouling paint	680	Other	654
Felt manufacture	493	Total	[1] 23,200

[1] Items are upon a partial coverage basis and do not add to total, which has been increased to cover total consumption.
[2] Largely for munitions other than fulminate.
[3] Use of virgin metal in the preparation of redistilled. The breaking down of this quantity would add substantially to industrial and control instruments and lesser amounts to dental preparations, electrical apparatus, and laboratory, pharmaceutical, and other uses.

STOCKS

Inventories of mercury in the hands of consumers and dealers amounted to about 12,400 flasks at the end of 1941 compared with 14,100 flasks at the end of 1940. These stocks do not include metal held by the Metals Reserve Co. and the Procurement Division of the Treasury Department and are largely exclusive of metal in the hands of companies that consume redistilled mercury only. Stocks held by the last group totaled 1,600 flasks at the end of 1941, but data are not available for the end of 1940. Stocks at mines that reported monthly to the Bureau of Mines aggregated 439 flasks compared with 607 flasks at the end of 1940.

REVIEW BY STATES

Production in the United States in 1941 rose 19 percent over that in 1940, which, in turn, was double the output in 1939. Largest percentage gains were made in Texas, Arkansas, and California, with Arizona also advancing. Less metal was recovered in Nevada, Alaska, Idaho, Washington, and Utah. San Benito and Lake Counties, Calif., ranked first and second as mercury-producing counties, followed by Douglas County, Oreg., and Sonoma County, Calif. New Idria and Bonanza were the two largest producing mines. The principal producing mines in 1941 were as follows:

Arizona—Gila County, Ord group; Maricopa County, Pine Mountain mine.
Arkansas—Clark County, Caddo mine; Pike County, Parker Hill and Superior mines.

California—Contra Costa County, Mount Diablo mine; Lake County, Great Western, Mirabel, and Sulphur Bank mines; Napa County, Oat Hill and Knoxville mines; San Benito County, New Idria (including San Carlos) mine; San Luis Obispo County, Oceanic and Klau mines; Santa Barbara County, Falcon (Santa Ynez) mine; Santa Clara County, New Almaden mine and dumps; Sonoma County, Contact, Great Eastern, and Mount Jackson mines; Yolo County, Reed mine.

Idaho—Washington County, Idaho-Almaden mine.

Nevada—Humboldt County, Blue Bird, Blue Can, and Cordero mines; Pershing County, Mount Tobin mine.

Oregon—Douglas County, Bonanza mine; Jefferson County, Horse Heaven mine; Malheur County, Bretz and Opalite mines.

Texas—Brewster County, Chisos and Big Bend mines; Presidio County, Fresno mine.

These 33 mines produced 85 percent of the United States total. The 29 most important mines produced 86 percent of the total in 1940 and 16 produced 88 percent in 1939.

Mercury produced in the United States, 1938–41, by States

Year and State	Producing mines	Flasks of 76 pounds	Value [1]
1938:			
California	52	12,277	$926,545
Nevada	17	336	25,358
Oregon	13	4,610	347,917
Alaska, Arkansas, Texas, and Washington	9	768	57,961
	91	17,991	1,357,781
1939:			
Arkansas	5	304	37,834
California	59	11,127	1,156,540
Nevada	25	828	86,062
Oregon	14	4,592	477,293
Arizona, Idaho, and Texas	4	1,722	178,985
	107	18,633	1,936,714
1940:			
Alaska	1	162	28,653
Arizona	6	740	130,884
Arkansas	10	1,159	204,992
California	70	18,629	3,294,911
Nevada	42	5,924	1,047,778
Oregon	23	9,043	1,599,436
Utah	1	53	9,374
Idaho, Texas, and Washington	6	2,067	365,590
	159	37,777	6,681,618
1941:			
Arizona	5	873	161,522
Arkansas	19	2,012	372,260
California	87	25,714	4,757,604
Nevada	54	4,238	784,115
Oregon	21	9,032	1,671,101
Utah	1	19	3,515
Alaska, Idaho, Texas, and Washington	10	3,033	561,166
	197	44,921	8,311,283

[1] Value calculated at average price at New York.

Alaska.—Mellick & Halverson produced mercury at the Red Devil mine during 1941 in a 1½-ton retort. The retort was idle for the winter, and the operators reported that a 30-ton Allis-Chalmers rotary was on the ground ready for installation. Two small lots of cinnabar were shipped to the United States for treatment.

Arizona.—Increased activity in Arizona carried the 1941 mercury production to a new peak for recent years. The output of 873 flasks was recovered largely at the Pine Mountain mine, Ord group, and Sunflower mine, as in 1940; smaller amounts came from two other operations. Productive operations are believed to have been confined to Gila and Maricopa Counties.

Arkansas.—A record-breaking number of properties took part in the production of an unprecedented quantity of mercury in 1941—19 mines having contributed 2,012 flasks. The mines are in Pike and Clark Counties. Many of the operations were very small, as is indicated by the fact that six mines supplied 1,777 flasks of the 1941

total. Large producers included the Caddo, Gap Ridge, Parker Hill, Superior, Big Six, and U. S. Mercury. The Mid-Continent mine, one of the larger producers in the past, was idle at the end of 1941.

California.—The supremacy of California as a mercury-producing State has never been challenged. It led by a substantial margin again in 1941, with 25,714 flasks, representing 57 percent of the national total.

Sixteen counties contributed the total for the State; chief among them, in order of importance in 1941, were San Benito, Lake, Sonoma, Santa Clara, San Luis Obispo, and Napa. Their output ranged from over 6,000 flasks to somewhat less than 2,000. In these counties, properties that have been supplying large amounts of metal in recent years—New Idria, Sulphur Bank, Mirabel, Great Western, Mount Jackson, New Almaden (mine and dumps), Klau, Oceanic, Oat Hill, and Knoxville—continued to stand out as large contributors. Other well-known mines in these counties that joined the leading producing properties in 1941 are the Great Eastern and Contact. Large producers in other counties include the Mount Diablo mine in Contra Costa County and the Reed in Yolo County.

The Manzarita and Dewey mines in Colusa County were active in 1941. New concentrating equipment was being installed at Manzanita at the end of the year.

In Contra Costa County the Bradley Mining Co. treated 19,201 tons of ore in its 50-ton Gould rotary at the Mount Diablo mine and produced 1,506 flasks of mercury.

Five mines in Fresno County were producing mercury in 1941, but their total was small.

A small output of metal was recovered from dumps in Inyo County and from two mines in Kings County.

Lake County ranked second only to San Benito in production of mercury in the United States during 1941. The Sulphur Bank mine dominated county output; an important amount also came from the Mirabel, followed by the Great Western and Abbott mines, and the Otto, Midway, and three others also were active. At the Sulphur Bank mine, 18,391 tons of ore were mined and treated in a 50-ton rotary kiln and 4,022 flasks of mercury were recovered. The Great Western mine produced 8,148 tons, of which 6,600 were treated in a 20-ton Herreshoff furnace, yielding 356 flasks of metal. The plant was burned and rebuilt in 1941. The mine and plant are described in the January 1941 issue of Compressed Air Magazine. Extensive diamond drilling and the usual drifting and cross-cutting were reported at the Mirabel mine. Plans were made during the year for reopening the Helen and Red Elephant mines; a new 3- by 40-foot Gould rotary furnace has been installed at the latter.

Activity at the Red Hawk mine in Modoc County resulted in the output of a very small quantity of mercury before the lease was abandoned.

A small quantity of metal was produced at the G. W. D. mine, Monterey County, in 1941.

The Oat Hill, Knoxville, Oat Hill Extension, and Aetna mines all old, familiar names, ranked above other producing properties in Napa County in 1941. The only output from the Knoxville mine in 1940 was from dumps. The Oat Hill treated 24,537 tons of ore in an 80-ton Gould rotary furnace in 1941 and produced 1,044 flasks of mercury,

and the Knoxville treated 1,126 tons of ore and 7,190 tons of dump material in a 40-ton Gould rotary to recover 69 and 389 flasks, respectively. Zack Anderson milled 2,400 tons of ore and recovered 147 flasks in retorts. Aetna's production was made in a 50-ton rotary furnace. Other producing properties included the Toyon, Corona, Manhattan, Twin Peaks, Washington dumps, and several operations on James Creek. Late in 1941 or early in 1942 the Corona mine passed under control of the Twin Peaks Mining Co., which planned to develop a larger-tonnage operation there. This company reported installation of a 70-ton rotary kiln and Diesel electric plant at the Twin Peaks mine in 1941. The Aetna Extension mine, lying between the Oat Hill and Aetna, was taken over by Atkins, Kroll & Co., and production early in 1942 was anticipated. Equipping and development of the Bella Oakes mine were begun in January 1942, and production was scheduled to start 2 months later.

San Benito County led all other counties in the United States in mercury production in 1941. The New Idria mine, as usual, outranked by an enormous margin all other mines in the county and easily led all others in the State, maintaining its place as one of the two leading producers in the country. The Aurora, Wonder, Star Nos. 1 and 2, Stayton, Lea-Grant, Yturriarte, Loneoak, Panoche (Valley View), El Rey, and Clear Creek (including Andy Johnson and Fourth of July) mines also were productive in 1941. The Lea-Grant mine (Lily Berg, Goodall Estate, and Ortiz properties) produced 194 flasks in 1941 from 3,804 tons of ore treated in its new 60-ton Gould rotary furnace.

The Klau mine was the outstanding producer in San Luis Obispo County, with a yield of 1,358 flasks from 14,047 tons of ore mined and treated; a new 70-ton Gould rotary furnace was installed in 1941 to supplement the 40-ton plant already in operation there, and a new shaft was being sunk to the 500-foot level. The Oceanic mine was second in importance; other producers were the Deer Trail, Little Bonanza, Buena Vista (Mahoney), Polar Star, Rinconada, and La Libertad.

Almost all of the output of Santa Barbara County came from the Red Rock and Falcon (Santa Ynez) mines. There are three rotary furnaces at the Falcon property, two of 30 tons capacity each and one of 50 tons. A newly installed Gould rotary was put into operation at the Red Rock mine. Press reports indicated that this plant was moved to California from the Blue Can mine in Humboldt County, Nev.

Activity at the famous New Almaden mine overshadowed all other operations in Santa Clara County during 1941; independent operations on the New Almaden dumps produced considerable metal. Other producers included the Guadalupe mine and several smaller operations.

The only mercury property known to have produced in Siskiyou County during 1941 is the Great Northern, where output was made in a new 50-ton Nichols Herreshoff furnace.

The rise of Sonoma County to third place among the mercury-producing counties in 1941 was due largely to reopening of the Mount Jackson mine in 1940 and of the Great Eastern in 1941 and to increased production at the Contact. Development of the Great Eastern mine included installation of a new 100-ton Gould rotary furnace. This plant treated 13,528 tons of ore and recovered 503 flasks of mercury, and the 75-ton Mount Jackson plant treated 29,068 tons and produced

1,625 flasks. Outstanding among the other producing mines were the Cloverdale, Culver-Baer, and Star Springs. The Socrates, Prospect, and seven other properties yielded the remainder of the county output.

The Altoona and Shasta Lily mines were the only known producers in Trinity County during 1941. Altoona's output is made in a 50-ton rotary.

A 50-ton rotary furnace was reported under construction at the end of 1941 at the Adobe mine in Stanislaus County.

The Bradley Mining Co. produced and treated 3,145 tons of ore to recover 784 flasks of mercury at the Reed mine in Yolo County. A 10-ton rotary was in operation during 1941, and a new 50-ton plant was expected to be completed in February 1942. Some mercury was produced from dump material at the Harrison.

Idaho.—Considerable exploratory work was carried on in Idaho during 1941, and two or three properties were reported to be on the verge of production at the close of the year. The Idaho-Almaden mine near Weiser was the only producing property, however, as in 1940 and 1939. A new Gould rotary of 100 tons rated capacity was installed at the Hermes mine in the Yellow Pine district, Valley County, by Bonanza Mines, Inc.; this property was obtained from the United Mercury Mines Co.

Nevada.—Production of mercury fell from 5,924 flasks in 1940 to 4,238 flasks in 1941 but continued well above the levels of other recent years. The decline was due largely to lowered rates of output in Humboldt and Mineral Counties, explained (in part, at least) by exhaustion of known ore reserves.

The Wild Horse mine in Churchill County was again productive; it yielded 106 flasks in 1941 from the treatment of 945 tons of ore. All operations were suspended in September, however, and no further production was reported contemplated; the Gould rotary furnace was removed.

Five mines in Elko County produced in 1941; the Butte (Bowers-Rand) had the largest output.

More metal was produced at the Red Rock than at any other mine in Esmeralda County. Ore from the Container was treated in the furnace at Red Rock. Two small properties also contributed to the county total.

Mercury output in Humboldt County dropped from the large quantity (2,713 flasks) produced in 1940 to 2,226 flasks in 1941. The largest contributor in 1941 was the Cordero mine, a newly developed property that began to treat ore in a newly installed 100-ton Nichols Herreshoff furnace in August. The output from this mine helped to offset a lowered rate of production in 1941 at some of the larger 1940 mines. As a whole the Blue Can, Blue Bird, and Wootan & McCown mines, operated by McAdoo interests, led Cordero by a considerable margin. Chief among the other producing mines were the Red Ore, Cahill, and Blue Bucket (Baldwin).

Eleven mines in Mineral County reported production; by far the largest part came from the Mina Development Co. property.

Six mines in Nye County were active during 1941. Magee Mercury, Inc., which is operating the Great Eastern mine in Sonoma County, Calif., began to develop the Horse Canyon mine and installed a 25-ton Gould rotary furnace purported to have come from the Wild

Horse mine in Churchill County. Ore from the San Pedro mine was shipped for treatment to the Red Rock mine in Esmeralda County. The Van Ness and three others also produced.

Mount Tobin dominated production in Pershing County. This property produced 6,684 tons of ore that yielded 626 flasks of mercury. In February 1942 the mine was reported worked out, and production was discontinued. The El Dorado mine produced 100 flasks in a Rossi retort during 1941 but was reported as closed on November 28. The Goldbanks mine also made an output and at the end of the year was under lease to the Bradley interests. Five other mines, including the Red Bird, were productive. Considerable activity that did not result in output during 1941 was reported at other properties; these include the old Pershing mine that last produced in 1930.

Oregon.—Oregon's total output of mercury in 1941 was within a few flasks of its 1940 production and double that in 1939. The Bonanza mine, Douglas County, again towered above other producers; the Horse Heaven in Jefferson County and the Bradley properties (Bretz and Opalite) in Malheur County also made important contributions to the total.

The Oak Grove and D. E. Kiggens properties in Clackamas County produced small amounts in 1941.

Nine properties were engaged in productive activity in Crook County; the Taylor Ranch (Whiting) and Staley and Culbertson ranked highest.

As already stated the Bonanza mine, Douglas County, was the dominant producer in Oregon and one of the two largest in the country. It was the only producing mine in the county.

Three properties in the Steens Mountain district, Harney County, reported an output for 1941. For many years this area has been known to contain mercury, but it did not produce until 1939. It has been described by Ross.[6]

The Roxana Group in Jackson County recovered a small quantity of metal in 1941.

The Horse Heaven mine in Jefferson County is the second-largest producer in Oregon. The Axehandle mine in this county also produced in 1941.

A little mercury was produced at the Lucky Boy No. 1 mine in Lake County in 1941.

At the old Black Butte mine in Lane County 19,733 tons of ore were treated, yielding 292 flasks of mercury, in 1941. This mine has had a long record of production and its locality is one of those picked for Bureau of Mines exploration work.

The only output in Malheur County during 1941 was from the Bretz and Opalite properties, operated by the Bradley interests. The Opalite mine produced 13,265 tons of ore that yielded 434 flasks of mercury. Bretz ore, totaling 4,862 tons, was hauled to the Opalite 80-ton rotary kiln for treatment and yielded 498 flasks.

Texas.—All the mercury produced in Texas during 1941 came from the Terlingua region, Brewster and Presidio Counties. Producing properties in Brewster County were the Chisos, Rainbow, Big Bend, Texas Almaden, Gard, and Black Mesa; in Presidio County the Fresno was active. The output at all mines except the Gard was from furnace operations.

[6] Ross, C. P., Work cited in footnote 3.

Utah.—The Congar Hill mine, Tooele County, produced 19 flasks of mercury from 76 tons of ore in 1941.

Washington.—Mercury was produced by the Roy Mining Co. in the Morton district, Lewis County.

FOREIGN TRADE [7]

Imports of mercury for consumption were 7,740 flasks in 1941 compared with the insignificant total of 171 flasks in 1940. Only 104 flasks of the 1941 total were credited to the first 7 months of the year. The benefits of the July agreement with Mexico, discussed elsewhere in this report, did not become evident in import statistics until November. During November and December, imports for consumption aggregated 6,861 flasks, of which Mexico supplied 6,651 flasks; the remainder came from Canada.

General imports, a better measure of the physical movement of imports than imports for consumption, amounted to 7,478 flasks in 1941 compared with 1,861 flasks in 1940.

Mercury imported into the United States, 1937–41, by countries

Country	1937		1938		1939		1940		1941	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
Canada									59,633	$130,468
Hong Kong	5	$5					3	$6		
Italy	747,266	649,406	84,454	$50,434	25,528	$29,818	228	316		
Mexico	116,497	104,730			42,745	61,313	9,698	13,681	520,692	1,171,752
Spain	535,156	440,804	95,068	82,176	197,671	245,613	3,042	3,958	7,903	6,373
United Kingdom	38,788	33,046								
	1,437,712	1,227,991	179,522	132,610	265,944	336,744	12,971	17,961	588,228	1,308,593

In addition to the mercury received from Mexico in the form of metal during 1941, antimony-mercury concentrates imported from that country yielded 1,300 flasks during the year. This latter class of imports is not shown separately in foreign trade statistics[8].

Imports of mercury compounds were virtually nonexistent during 1941, as is shown by the table that follows.

Mercury compounds imported for consumption in the United States, 1940–41

Compound	1940		1941	
	Pounds	Value	Pounds	Value
Chloride (mercurous) (calomel)	19,513	$16,374	25	$83
Mercury preparations (not specifically provided for)	21,863	15,362	24	140
Oxide (red precipitate)	9,000	9,234		
Vermilion reds (containing quicksilver)	14,332	13,114	25	9
		54,084		232

Exports fell from the high total of 9,617 flasks reached in 1940 to 2,590 flasks in 1941; the aggregate for 1941, however, was larger than in any other year since 1931. The abnormal relationship of international to domestic prices in 1931 favored exportation of the metal. International prices favored the exportation of mercury again in 1941,

[7] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

but domestic export restrictions and disruption of international trade routes rendered normal economic laws invalid in that year.

In 1941 little more than one-tenth of the amount shipped to the United Kingdom in 1940 (598 flasks compared with 5,178) was destined to that nation, but it continued to get more than any other country. The shipment of mercury from Canada, the only important source of mercury in the British Empire, to the United States in 1941 would seem to indicate either a relatively adequate supply of metal in the United Kingdom or a greater need for mercury products than for the metal itself. Japan received no mercury from the United States in 1941 but had the second-largest amount in 1940—1,598 flasks. The only sections of the world that received larger quantities in 1941 than in 1940 were the Asiatic Continent and islands (other than Japan), to which 629 flasks were shipped compared with 181 flasks in 1940.

Mercury exported from the United States, 1937–41

Year	Pounds	Value	Year	Pounds	Value
1937	34, 485	$37, 165	1940	730, 877	$1, 743, 149

WORLD PRODUCTION

The inability to obtain data covering activity in Spain and Italy, the world's largest sources of production of mercury, makes it impossible to compile a reliable estimate of world production. As the mines in these areas are either under Axis domination or friendly to the Axis Powers, ample supplies are assured enemies of the United States, whereas supplies for the United Nations have presented more of a problem.

World trade conditions have contributed to greatly expanded production in the United States, Mexico, and Canada during the past 2 years and have prompted prospecting for and development of additional sources in several other Western Hemisphere countries. Output in the United States during 1941 was 44,921 flasks compared with 18,633 in 1939, and Mexico produced 23,137 flasks in 1941 compared with 7,376 in 1939. Canada, during this period, rose from an insignificant producer to a position as the only important source in the British Empire. Interest regarding mercury mining has been reported recently in Honduras, Brazil, Chile, Peru, and Venezuela. In connection with the increased emphasis on finding additional sources of mercury, technical representatives of the United States Government have examined mercury prospects in Mexico and other countries of the Western Hemisphere.

Available information for various countries is reviewed on the following pages.

World production of mercury, 1937–41, by countries

[Compiled by B. B. Waldbauer]

[1 metric ton=29.008 flasks of 76 pounds]

Australia.—The Metal Bulletin (London) of September 2, 1941, indicated that the mercury property at Kilkivan, Queensland, might double its plant capacity, which had been about 40 pounds a week. Exploitation of adjoining properties was said to be under way.

Development work is also reported to be in progress elsewhere on the continent.

Canada.—Information regarding production of mercury in Canada is again confidential. It is known, however, that since 1939 production in this country has turned sharply upward. The increased output is from the Pinchi Lake property of the Consolidated Mining & Smelting Co. of Canada, Ltd. Production of mercury at the property of Empire Mercury Mines in the Pinchi Lake district is reported to have been discontinued owing to operating difficulties.

Chile.—Mercury ores are said to occur in the Provinces of Atacama, Aconcagua, and Coquimbo but are mined mainly in the last-named. The Compania Minera Pumitaqui, a Chile owned and managed corporation, is reported to be the only concern producing mercury for export. Its property is, however, primarily a gold-copper mine. The output in midyear 1941 was said to be a little over 100 tons of mercury concentrates (containing 2½ to 3 percent mercury) a month, and increased production was in prospect. At that time Japanese interests were bidding for the metal.

China.—Mercury was produced in Kweichow, Hunan, and Szechuan Provinces in 1941; the major part of the production of probably more than 6,000 flasks came from Kweichow. Figures from a reliable source indicated that more than 4,000 flasks were shipped to Russia in June, August, and December and probably additional quantities at other times. Some metal was shipped to India and small quantities to other countries.

Italy and Spain.—Lack of recent data makes it impossible to bring previous annual reports on mercury up to date with regard to Italy and Spain, the leading sources of this commodity. It can be repeated, however, that these nations can doubtless produce approximately 70,000 flasks apiece should demand from available customers require it. Accessibility of the Axis Powers to these outstanding producers of mercury appears to assure very ample supplies to all but Japan, which is shut off by shipping difficulties.

Japan.—The South Africa Mining & Engineering Journal of August 30, 1941, reported that the Yamato Mercury Mining Co. was planning to increase its present rate of mercury production, given as 1,500 to 2,000 flasks annually. Early in 1941, Japan was receiving large quantities of mercury from Mexico and was negotiating for the purchase of Chilean metal. Japanese offers considerably exceeded prices prevailing in the United States. The agreement between the United States and Mexican Governments in July 1941 stopped shipments of Mexican metal to Japan.

Mexico.—Our neighbor republic is one of the few important mercury-producing countries in the world whose production data are available for publication. These show that output during 1941 amounted to 23,137 flasks, double the production of 11,653 flasks attained in 1940, which itself was sharply above the 7,376 flasks recovered in 1939. The largely increased quantities made available during the first 7 months of 1941 went mainly to Japan, to which was consigned 93 percent of the 17,037 flasks exported during that period.

In July an agreement was reached with the Mexican Government whereby the United States was to obtain the surplus production of certain strategic commodities, including mercury, placed under export control by the Mexican Government. Under its terms, this country is obliged to acquire surpluses over and above metal sold through regular commercial channels to customers in the Western Hemisphere that had export limitations similar to the Mexican regulations. The agreement was to be in effect for 18 months and applies to quantities up to 125 percent of exports of such commodities during the 18-month period ended July 1, 1941. Both production and export official totals were much lower after the agreement, but by December they had advanced to figures resembling activity earlier in the year. Data on production and exports in 1941 follow:

Mercury produced in and exported from Mexico in 1941, by months, in flasks of 76 pounds

Month	Production	Exports	Month	Production	Exports
January	1,676	1,666	August	715	705
February	2,446	2,446	September	863	858
March	1,924	1,914	October	549	543
April	3,841	3,796	November	1,072	1,053
May	1,603	1,569	December	2,726	2,726
June	2,738	2,695			
July	2,984	2,951		23,137	22,922

Since July most of the metal exported has come to the United States, although smaller quantities have been consigned to Argentina, Brazil, Colombia, Costa Rica, Cuba, and Uruguay; 62 flasks went to Japan in August.

The following States are reported to contain mercury mines or occurrences of mercury: Aguascalientes, Chihuahua, Durango, Guanajuato, Guerrero, Hidalgo, Jalico, Mexico, Michoacan, Morelos, Oaxaca, Queretaro, San Luis Potosi, and Zacatecas.

The famed Trinidad mine is in the State of San Luis Potosi, and the Huitzuco mine is in Guerrero.

The Pacific Foundry Co., Ltd., of Los Angeles, Calif., reported that it had constructed three 30- to 40-ton and one 20- to 25-ton Nichols Herreshoff plants and one additional retort in Mexico in 1941.

New Zealand.—Mercury is reported being produced by Mercury Explorations, Ltd., at Puhipuhi, after 2 years of preparatory work. The property is situated in barren country traversed by a cinnabar-bearing belt, but commercial ore is found only in scattered areas and pockets. Ore is loaded by mechanical shovel into motor trucks and transported to the treatment plant—an oil-fired, rotary furnace. Recovery of mercury from low-grade deposits at Ngawha and elsewhere was being investigated in 1941.

Peru.—Although little mercury has been produced in Peru in recent years, at one time one of the largest producing properties in the world was active there. Most of the past production has come from the famous Santa Barbara mines, a few miles south of Huancavelica. Wm. C. Vanderburg, foreign mineral specialist of the Bureau of Mines, recently supplied the following data regarding mercury in Peru.

The deposits were discovered in 1570 and up to 1908 had produced 51,362 tons of mercury, equivalent to 1,489,498 flasks (76-pound). This output exceeds that of the New Almaden property in California, largest source of mercury in the United States, which up to 1930 had produced 1,039,675 flasks. During the colonial period, the Santa Barbara deposits supplied not only the mining industry of Peru but also Bolivia, Chile, and Mexico, where the patio process of silver amalgamation was employed. The decadence in the early days of the mines is attributed to exhaustion of the richer ores and to the discovery of mercury in California about 1850. Since 1901 repeated attempts have been made to revive the mines, generally with little success. As current prices for mercury are high, the old workings are being sampled by E. E. Fernandini with the object of treating the lower-grade ores on a large scale. It is reported that there is a large tonnage of low-grade ore containing 0.1 to 0.2 percent mercury; if this is confirmed by sampling, tentative plans call for the erection of a plant capable of treating 500 tons of ore daily. The mercury deposit in the Chonta district, Department of Huanuco, has been under development for the past year by Panaminas, Inc., subsidiary of Ventures, Ltd., of Canada. It is reported that enough ore reserves have been blocked out to justify the erection of a 20-ton-daily-capacity Gould furnace, which has been ordered. Several beds of coal that can be used as furnace fuel occur near the deposit.

Union of South Africa.—According to the Metal Bulletin (London) of May 23, 1941, production of mercury on a small scale was started at Monarch Kap on the Murchison Range, Northern Transvaal, in July 1940. During the latter half of 1940, 3,329 pounds (44 flasks) of mercury were produced, and late in 1941 output was reported to be increasing. Mercury for consumption in South Africa has been previously supplied chiefly by imports from Spain and Italy, according to an article in the March 29, 1941, issue of The Chemical Age. This magazine gives imports of mercury as ranging from 600 to 1,100 flasks a year for 1937 to 1939. The metal is used in gold mining, for the manufacture of explosives, pigments, and scientific instruments, and in medicine; some difficulty in obtaining necessary supplies was anticipated.

Venezuela.—Compania Anonima Minerales de San Jacinto was organized in Caracas in April 1941 to operate a cinnabar mine near La Mesa, Muncipio Chiquinquira, Distrito Torres, in the State of Lara. The mine was expected to reach a monthly capacity of 200 tons of ore. Fifty tons were shipped to the United States for treatment. According to the Anglo-American Metal & Ferro-Alloy Corporation, which purchased the ore, careful sampling, assaying, and rechecking the actual analysis of the ore showed that it contained no more than 2 percent mercury—considerably less than was anticipated. The producing company expected to treat the ore at the mine beginning in January 1942, using retorts made from oil-well casings.
